Introduction

- This presentation provides a summary of assumptions pertaining to sources of error in 802.1AS time synchronization
  - A network that satisfies these assumptions will be capable of meeting the desired time synchronization accuracy of 1 μs over a maximum of 7 hops
  - It is intended that, after discussion and editing, these assumptions will be copied to the master list of AVB assumptions [1]
- This work was requested in the April 30, 2007 AVB timing call, after an initial discussion of sources of error based on [2]

Assumptions Relevant to AVB Time Synch

- Network diameter
  - Maximum diameter of any spanning tree of the network is 7 hops
- Local oscillator quality
  - ±100 ppm or better free-run accuracy
  - Rate for 100 Mbit/s Ethernet is ≥ 25 MHz
  - Rate for GbE is ≥ 125 MHz
- PTP clock quality
  - End-point time synchronization accuracy is 1 μs or better over 7 hops
    - i.e., any 2 PTP clocks separated by at most 7 hops differ by no more than 1 μs
- Assumptions on error sources present in network, to meet the above time synchronization requirement for PTP clocks
  - Maximum frquency drift rate of local oscillator ≤ 1 ppm/s (this assumption, combined with maximum frequency offset of ±100 ppm, results in maximum time synchronization error due to this effect of < 1 ns
  - Effect of frequency measurement granularity is negligible
  - e.g., if 32 bits is used to express the measured frequency offset, the maximum frequency error due to this effect is 2.3×10^{-10}

Assumptions Relevant to AVB Time Synch (Cont.)

- Assumptions on error sources present in network, to meet the above time synchronization requirement for PTP clocks (Cont.)
  - Effect of PHY latency asymmetry and phase measurement granularity for 100 Mbit/s Ethernet
    - Any PHY latency asymmetry can be known as part of the design and compensated for to within 25% of the maximum allowable PHY latency
    - This means that of the allowable PHY latency asymmetry of IEEE 802.3 for 100BASE-X (table 24-3, plus additional 16 ns; see [2]) of 376 ns per hop, the maximum remaining uncertainty after compensation is 119 ns/hop, or 833 ns for 7 hops
    - The cumulative time synchronization error due to phase measurement granularity over 7 hops is 125 ns
      - This assumes that the variation of this error is sufficiently fast that, with a Sync interval between 10 ms and 100 ms, the effect of this variation can be reduced by endpoint filtering
    - All the above error components, taken together, leave a margin relative to the total 1 μs of approximately 40 ns

Assumptions Relevant to AVB Time Synch (Cont.)

- Assumptions on error sources present in network, to meet the above time synchronization requirement for PTP clocks (Cont.)
  - Effect of PHY latency asymmetry and phase measurement granularity for GbE
    - Any PHY latency asymmetry can be known as part of the design and compensated for to within 35% of the maximum allowable PHY latency
    - This means that of the allowable PHY latency asymmetry of IEEE 802.3 for 100BASE-X (table 40-14, plus additional 16 ns; see [2]) of 344 ns per hop, the maximum remaining uncertainty after compensation is 120 ns/hop, or 840 ns for 7 hops
    - The cumulative time synchronization error due to phase measurement granularity over 7 hops is 120 ns
      - This assumes that the variation of this error is sufficiently fast that, with a Sync interval between 10 ms and 100 ms, the effect of this variation can be reduced by endpoint filtering
    - All the above error components, taken together, leave a margin relative to the total 1 μs of approximately 40 ns
