Typical Enterprise Data Center

- Relatively small number of VLANs (<< 4K);
- VLAN identified by same VID throughout data center;
  - VID 38 might represent ‘web server traffic’ or ‘engineering organization’;
  - Static and global nature of VID allows it to be known to the Server Admin;
Scenario 1: Filter on (MAC, VID) pairs
VID Global and known to Server

• VDP Req instructs bridge to use the filter ((MAC A, VID 27) (MAC A, VID 34)) to identify traffic associated with VSI 1234 in order to apply VSI-type identified by VTID abc;
• This VDP message would carry a ‘MAC/VLAN Format’ value of ‘Basic MAC/VLAN Format’ = 00;
Scenario 2: Filter on VID list
VID Global and known to Server

- VDP Req instructs bridge to use the filter (VID 27, VID 34) to identify traffic associated with VSI 1234 in order to apply VSI-type identified by VTID abc;
- This VDP message would carry a ‘MAC/VLAN Format’ value of ‘VID-only format’ = 02;
- Same as scenario 1 except that VID list replaces list of (MAC, VID) pairs;
• Data Center providing *cloud services* likely to have >4K Service Instances;
  – Any one rack supports up to 4K;
• Global ID “Jack’s Garden Markets” is mapped to different VID at each rack boundary;
• Network Admin (vs. Server Admin) must control assignment of VID to Service Instance at each rack;
Scenario 3: Filter on (MAC, VID) pairs; VID assigned by *Bridge*

- VDP Req instructs bridge to use the filter ((MAC A, GroupName1) (MAC A, GroupName2)) to identify traffic associated with VSI 1234 in order to apply VSI-type identified by VTID abc;
- Bridge determines that GroupName1 is associated with VID 27 and GroupName2 is associated with VID 34 in the local rack; The bridge will use the filter ((MAC A, VID 27), (MAC A, VID 34));
- Bridge supplies server with the local VID values associated with the GroupNames;
- The VDP Req carries a ‘MAC/VLAN Format’ value of ‘MAC/GroupName’ = 05 and the VDP Rsp carries a ‘MAC/VLAN Format’ value of ‘MAC/GroupName/VID’ = 06;
Scenario 4: Filter on VID list; VID assigned by Bridge

VDP Req (VSI 1234, VTID abc, fmt 03, Big Spot Cleaning, Jack’s Garden Markets)

VDP Rsp (VSI 1234, VTID abc, fmt 04, (Big Spot Cleaning, VID 27), (Jack’s Garden Markets, VID34))

- VDP Req instructs bridge to use the filter (GroupName1, GroupName2)) to identify traffic associated with VSI 1234 in order to apply VSI-type identified by VTID abc;
- Bridge determines that GroupName1 is associated with VID 27 and GroupName2 is associated with VID 34 in the local rack; The bridge will use the filter (VID 27, VID 34);
- Bridge supplies server with the local VID values associated with the GroupNames;
- The VDP Req carries a ‘MAC/VLAN Format’ value of ‘GroupName’ = 03 and the VDP Rsp carries a ‘MAC/VLAN Format’ value of ‘GroupName/VID’ = 04;
### Scenario 5: Filter specified by VSI-type

- **VDP Req** provides *no* filter info;
- Bridge finds filter info in VSI-type; say, (VID 27, VID 34);
- Bridge determines that **GroupName1** is associated with VID 27 and **GroupName2** is associated with VID 34 in the local rack; The bridge will use the filter (VID 27, VID 34);
- Bridge supplies server with the local VID values associated with the **GroupNames**;
- The **VDP Rsp** carries a ‘MAC/VLAN Format’ value of ‘**GroupName/VID**’ = 04;
Summary

- New flows for cloud service case where VID associated with a particular Service Instance can vary from rack to rack;
  - Server can no longer specify VID in VDP
- Flows same as existing except server specifies global ‘GroupName’ instead of local ‘VID’;
  - Bridge replies to server with GroupName \(\leftrightarrow\) VID mapping that server uses for data traffic;
- Additional case in which filter is not specified in VDP but obtained from VSI-type;
  - Bridge replies with local VID value corresponding to GroupName found in VSI-type;
- New flows imply no change to VDP state machines;
- *Does* require additional values of the ‘MAC/VLAN Format’ field;
  - change is *fully specified* in accompanying document VidInVdpRsp
- This is a very simple but essential feature if cloud service data centers are to be supported by Qbg;
