## 5 Abstract

This document describes use cases for industrial automation, which have to be covered by the joint IEC/IEEE TSN-IA Profile for Industrial Automation.

13 Log

V0.1-V0.3		working drafts
V0.4	2018-03-02	Revised after circuit meeting
V0.5	2018-03-07	Revised and presented during Chicago meeting
V0.6	2018-04-12	Elaborated additional use cases from Chicago

Added new use cases:

- Control loops with bounded latency
- Drives without common application cycle but common network cycle
- Redundant networks
- Vast number of connected stations
- Digital twin

V0.61	2018-04-30	Presented at ad-hoc meeting Munich Revised after Munich ad-hoc review - Added Interoperability clause (2.1) - Reworked industrial automation traffic patterns clause (2.3.1) - Added VLAN requirements clause (2.4.11.1) - Added private machine domains sub-clause (2.5.2)
V0.7	2018-06-09	Comment resolution Interim Pittsburgh May 2018
V1.0	2018-07-20	Added Plenary San Diego July 2018 contributions and comments: - TSN domain definition - control loop clause

### 183 1 Terms and Definitions

#### 184 1.1 Definitions

Reconfiguration

- Any intentional modification of the system structure or of the device-level content, including updates of any type
- Ref: IEC 61158- Type 10, dynamic reconfiguration
- Document to be provided by PI/PNO: Guidelines for highavailability

(Process) disturbance

- Any malfunction or stall of a process/machine, which is followed by production loss or by an unacceptable degradation of production quality
- Ref: IEC 61158 Failure
- Ref. ODVA: Unplanned downtime
- Document to be provided by PI/PNO: Guidelines for diagnosis

Operational \_state of a plant (unit)/machine

Normal state of function and production of a plant(unit)/machine

Maintenance \_state of a plant (unit)/machine

Planned suspension or partial suspension of the normal state of function of a plant(unit)/machine

Stopped \_state of a plant (unit)/machine

Full non-productive mode of a plant(unit)/machine

Convergent network concept

All Ethernet-based devices are able to exchange data over a common infrastructure, within defined QoS parameters

Device End station, bridged end station, bridge

DCS Distributed Control System

Transmission selection

algorithms

A set of algorithms for traffic selection which include Strict Priority, the Credit-based shaper and Enhanced Transmission Selection.<sup>1)</sup>

Preemption

The suspension of the transmission of a preemptable frame to allow one or more express frames to be transmitted before transmission of the preemptable frame is resumed.<sup>1)</sup>

Enhancements for scheduled traffic

A Bridge or end station may support enhancements that allow transmission from each queue to be scheduled relative to a known timescale.<sup>1)</sup>

Time-Sensitive Stream

A stream of traffic, transmitted from a single source station, destined for one or more destination stations, where the traffic is sensitive to timely delivery, and in particular, requires transmission latency to be bounded.<sup>1)</sup>

TSN domain

A quantity of commonly managed industrial automation devices; A set of stations (end stations and/or Bridges), their Ports, and the attached individual LANs that transmit Time-Sensitive Streams using TSN standards which include Transmission Selection Algorithms,

Use Cases IEC/IEEE 60802 Page 9 of 64

192 193

191

There is no generally accepted definition of the term "Cyber-Physical System (CPS)". A report of Edward A. Lee [1] suitably introduces CPS as follows: "Cyber-Physical Systems (CPS) are integrations of computation with physical processes. Embedded computers and networks monitor and control the physical processes, usually with feedback loops where physical processes affect computations and vice versa."

Cyber-Physical Systems are the building blocks of "smart factories" and Industry 4.0. Ethernet provides the mechanisms (e.g. TSN features) for connectivity to time critical industrial applications on converged networks in operational technology control levels.

Ethernet with TSN features can be used in Industrial Automation for:

- · Real-time (RT) Communication within Cyber-Physical Systems
- · Real-time (RT) Communication between Cyber-Physical Systems

#### A CPS consists of:

  - Router, and/or
  - Bridge.
- Other Ethernet devices:
  - Servers or any other computers, be it physical or virtualized,
  - Diagnostic equipment,
  - Network connectivity equipment.

## 221 2.1 Interoperability

Interoperability may be achieved on different levels. Figure 2 and Figure 3 show three areas, which need to be covered:

- network configuration (managed objects according to IEEE definitions), and
- stream configuration and establishment, and
- application configuration.
- The three areas mutually affect each other (see Figure 2).
- Application configuration is not expected to be part of the profile, but the two other areas are.
- The selection made by the TSN-IA profile covers Ethernet defined layer 2 and the selected
- 230 protocols to configure layer 2.
- 231 Applications make use of upper layers as well, but these are out of scope for the profile.
- 232 Stream establishment is initiated by applications to allow data exchange between applications. The
- 233 applications are the source of requirements, which shall be fulfilled by network configuration and
- 234 stream configuration and establishment.

245

A <u>TSN domain</u> is defined as a quantity of commonly managed industrial automation devices; it is an administrative decision to group these devices.

TSN Domain Characteristics:

Use Cases IEC/IEEE 60802 Page 11 of 64

- One or more TSN Domains may exist within a single layer 2 broadcast domain.
- A TSN Domain may not be shared among multiple layer 2 broadcast domains.
- Multiple TSN Domains may share a common universal time domain.
- Two adjacent TSN Domains may implement the same requirements but stay separate.

250 Typically machines/functional units (see Figure 1) constitute separate TSN domains. Production 251 cells and lines may be set up as TSN domains as well. Devices may be members of multiple TSN 252 domains in parallel.

Interrelations between TSN domains are described in 2.6.1.

Figure 4 shows two example TSN domains within a common broadcast domain and a common universal time domain. TSN domain 1 is a pure cyclic real-time domain, whereas TSN domain 2 additionally includes three overlapping isochronous domains.

268

269

270

Synchronization covering both universal time (wall clock) and working clock is needed for industrial automation systems.

Redundancy for synchronization of universal time may be solved with "cold standby". Support of "Hot standby" for universal time synchronization is not current practice - but may optionally be supported.

Redundancy for working Clock synchronization can be solved with "cold standby" or "hot standby" depending on the application requirements. Support of "hot standby" for working clock synchronization is current practice.

271 More details about redundancy switchover scenarios are provided in:

272 http://www.ieee802.org/1/files/public/docs2018/60802-Steindl-TimelinessUseCases-0718-v01.pdf.

2.3.2 Universal Time Synchronization

273 Universal time is used to plant wide align events and actions (e.g. for "sequence of events"). The 274 assigned timescale is TAI, which can be converted into local date and time if necessary. Figure 5 275 276 shows the principle structure of time synchronization with the goal to establish a worldwide aligned timescale for time. Thus, often satellites are used as source of the time. 277

**Use Cases IEC/IEEE** 60802 Page 12 of 64

287 288

289

290

291

Figure 5 – plant wide time synchronization

Note: "Global Time" or "Wall Clock" are often used as synonym terms for "Universal Time".

## 2.3.3 Working Clock Synchronization

Working Clock is used to align actions line, cell or machine wide. The assigned timescale is arbitrary. Robots, motion control, numeric control and any kind of clocked / isochronous application rely on this timescale to make sure that actions are precisely interwoven as needed. Figure 6 shows the principle structure of Working Clock synchronization with the goal to establish a line / cell / machine wide aligned timescale. Thus, often PLCs, Motion Controller or Numeric Controller are used as Working Clock source.

If multiple PLCs, Motion Controller or Numeric Controller need to share one Working Clock timescale, an all-time active station must be used as Working Clock source, also known as Grandmaster.

292

293

294295

296

Figure 6 – line/cell/machine wide working clock synchronization overlapping with a universal time domain

Working Clock domains may be doubled to support zero failover time for synchronization.

High precision working clock synchronization is a prerequisite for control loop implementations with low latency (see 2.4.2).

## 299 Requirements:

- High precision working clock synchronization;

  Maximum deviation to the grandmaster time in
  - Maximum deviation to the grandmaster time in the range from 100 ns to 1  $\mu$ s;
  - Support of redundant sync masters and domains;
  - Zero failover time in case of redundant working clock domains;

306

#### 2.3.4 Use case 01: Sequence of events

Sequence of events (SOE) is a mechanism to record timestamped events from all over a plant in a common database (on-premise database in Figure 1).

- 311 Application defined events are e.g. changes of digital input signal values. Additional data may be
- provided together with the events, e.g. universal time sync state and grandmaster, working clock
- 313 domain and value ...
- 314 SOE enables root-cause analysis of disruptions after multiple events have occurred. Therefore
- 315 SOE can be used as diagnostics mechanism to minimize plant downtime.
- 316 Plant-wide precisely synchronized time (see Figure 5) is a precondition for effective SOE
- 317 application.
- 318 SOE support may even be legally demanded e.g. for power generation applications.
- 319 Requirements:
  - · Plant wide high precision Universal Time synchronization;
  - . Maximum deviation to the grandmaster time in the range from 1 μs to 100 μs;
  - · Optional support of redundant sync masters and domains;
  - Non-zero failover time in case of redundant universal time domains;

## 2.4.1.2 Characterization of isochronous cyclic real-time and cyclic real-time

The following properties table is used to characterize in detail the traffic types of Use case 02: Control Loops with guaranteed low latency and Use case 03: Control Loops with bounded latency.

Table 2 – isochronous cyclic real-time and cyclic real-time traffic type properties

Property	Description		
Data transmission scheme	Periodic (P) - e.g. every N μs, or Sporadic (S) - e.g. event-driven		
Data transmission constraints	Indicates the traffic pattern's data transmission constraints for proper operation. Four data transmission constraints are defined:		
	<ul> <li>deadline: transmitted data is guaranteed to be received at the destination(s) before a specific instant of time,</li> </ul>		
	<ul> <li>latency: transmitted data is guaranteed to be received at the destination(s) within a specific period of time after the data is transmitted by the sending application,</li> </ul>		
	<ul> <li>bandwidth: transmitted data is guaranteed to be received at the destination(s) if the bandwidth usage is within the resources reserved by the transmitting applications,</li> </ul>		
	<ul> <li>none: no special data transmission constraint is given.</li> </ul>		
Data period	For traffic types that transmit <i>periodic</i> data this property denotes according to the <i>data transmission constraints</i> :		
	deadline: application data deadline period,		
	latency, bandwidth or none: data transmission period.		
	The period is given as a <i>range</i> of time values, e.g. 1µs 1ms.		
	For the <i>sporadic</i> traffic types, this property does not apply.		
Data transmission synchronized to network	Indicates whether the data transmission of sender stations is synchronized to the network cycle.		
cycle	Available property options are: <i>yes</i> or <i>no.</i>		

Property	Description		
Application synchronized to working clock	Indicates whether the applications, which make use of this traffic pattern, are synchronized to the working clock.		
	Available property options are: yes or no.		
Acceptable jitter	Indicates for traffic types, which apply data transmission with <i>latency</i> constraints, the amount of jitter, which can occur and must be coped with by the receiving destination(s).		
	For traffic types with <i>deadline</i> , <i>bandwidth</i> or <i>none</i> data transmission constraints this property is not applicable ( <i>n.a.</i> ).		
Acceptable frame loss	Indicates the traffic pattern's tolerance to lost frames given e.g. as acceptable frame loss ratio range.		
	The frame loss ratio value 0 indicates traffic types, where no single frame loss is acceptable.		
Payload	Indicates the payload data <i>type</i> and <i>size</i> to be transmitted. Two payload types are defined:		
	<ul> <li>fixed: the payload is always transmitted with exactly the same size</li> </ul>		
	<ul> <li>bounded: the payload is always transmitted with a size, which does not exceed a given maximum; the maximum may be the maximum Ethernet payload size (1500).</li> </ul>		

### 2.4.2 Control Loop Basic Model

**Control loops** are fundamental building blocks of industrial automation systems. Control loops include: process sensors, a controller function, and output signals. Control loops may require guaranteed low latency or more relaxed bounded latency (see 2.4.4) network transfer quality.

To achieve the needed quality for Control loops the roundtrip delay (sometimes called makespan, too) of the exchanged data is essential.

Figure 7 shows the whole transmission path from Controller application to Device application(s) and back. The blue and red arrows show the contributions to the e2e (end-to-end) latency respectively.

384 385 386

389

376

377

378

379

380 381

382

383

Figure 7 and Table 3 show three levels of a control loop:

- § Application within Talker/Listener,§ Network Access within Talker/Listener,
- § Network Forwarding within Bridges.

390 Network Access is always synchronized to a working clock.

Application may or may not be synchronized to the synchronized Network Access depending on the application requirements. Applications which are synchronized to Network Access are called "isochronous applications". Applications which are not synchronized to Network Access are called "non-isochronous applications".

Network Forwarding may or may not be synchronized to a working clock depending on whether the Enhancements for Scheduled Traffic (802.1Qbv) are applied.

396 397

395

Use Cases IEC/IEEE 60802 Page 17 of 64

	802.1.Qbv	Strict Priority	802.1Qbv	Strict Priority

### 2.4.3 Use case 02: Control Loops with guaranteed low latency

Control loops with guaranteed low latency implement an isochronous traffic pattern for isochronous applications, which are synchronized to the network access (see Table 3). It is based on a network cycle, which consists of an IO data Transfer time and a Control calculation time wherein the control loop function is executed.

Figure 8 shows the principle how network cycle, transfer time and application time interact in this use case. The control loop function starts for controllers and devices after the transfer time when all necessary buffers are available. A single execution of a control loop function ends before the next transfer time period starts. Thus, all frames must be received by the addressed application within the transfer time. An optimized local transmit order at sender stations is required to achieve minimal transfer time periods.

Use Cases IEC/IEEE 60802 Page 18 of 64

Figure 8 – network cycle and isochronous application (Basic model)

Figure 9 shows how this principle is used for multiple concurrent applications with even extended computing time requirements longer than a single application time within the network cycle time. When reduction ratio >1 is applied (see 2.4.5), the control loop function can be expanded over multiple network cycles (Control loop 2 with reduction ratio 2 and Control loop 3 with reduction ratio 16 in Figure 9).

Maximum available computation time for a Control loop with reduction ratio X:

X \* network cycle time - Transfer time - Application safety margin

Transfer of isochronous cyclic real-time, cyclic real-time and non-real-time data is processed in parallel to the various control loop functions - preserving the deadline requirement of the control loops.

A background task can additionally run, when free com time is available.

Figure 9 – Multiple concurrent isochronous control loops (Extended model)

Network cycle: transfer time (including safety margin) and application time (including safety margin)

Use Cases IEC/IEEE 60802 Page 19 of 64

Transfer time: period of time, wherein all necessary frames are exchanged between stations (controller, devices); the minimum transfer time is determined by the e2e latencies of the necessary frames; the e2e latency depends on: PHY-delays, MAC-delays, bridge-delays and send ordering. The transfer time is a fraction of the network cycle time.

For a given target transfer time the number of possible bridges on the path is restricted due to PHY-, MAC- and bridge-delay contributions.

Figure 10 to Figure 15 show variations of the basic model of Figure 8:

456

457

458

459

460

461 462

463 464 Figure 16 shows the isochronous cyclic operation model for guaranteed low latency.

Figure 16 – isochronous cyclic operation model

Isochronous cyclic operation characteristics:

Multiple applications (periodic tasks) with different application periods are supported. Applications are synchronized to working clock:

Devices: ÖController: Ö

Use Cases IEC/IEEE 60802 Page 21 of 64

Multiple application update times based on different reduction ratios are supported. Data transmission is synchronized to network cycle (WorkingClock):

Ö Devices: Ö Controller:

The single steps of the isochronous cyclic operation model are:

(1)

Controller periodic tasks are synchronized to the working clock. Example:

> Periodic task 01 period (t1) == network cycle period (t2). Periodic task 02 period == 8 \* network cycle period (t2).

> Periodic task\_03 period == 32 \* network cycle period (t2).

2

Device data transmission is synchronized to network cycle (Working Clock).

Device input data must reach controller within an application defined deadline. Controller application may check the timeliness (by means of additional data in the

payload, e.g. LifeSign model).

Controller application operates on local process image data. Local process image decouples communication protocol from application.

#### Additional:

Device input data must reach controller within a communication monitoring defined deadline (communication protocol). Communication disturbances are recognized and signaled asynchronously by communication protocol to application.

Controller output data transmission is synchronized to network cycle (Working Clock).

Controller output data must reach device within an application defined deadline. Device application may check the timeliness (by means of additional data in the

payload, e.g. PROFINET Isochronous Mode SignOfLife model – see [3]).

Device application operates on local process image data. Local process image decouples communication protocol from application.

#### Additional:

Controller out data must reach device within a communication monitoring defined deadline (communication protocol). Communication disturbances are recognized and signaled asynchronously by communication protocol to application.

High control loop quality is achieved by:

- Short network cycle times to minimize reaction time (dead time),
- equidistant network cycle times based on a synchronized working clock to ensure a defined reaction time,
- device signal processing and transfer coupled to synchronized working clock, and
- device and controller application (function) coupled to synchronized working clock.

isochronous mode: coupling of device and controller application (function) to the synchronized working clock

isochronous cyclic real-time: transfer time less than 20%/50% of network cycle and applications are coupled to the working clock.

## Table 4 – isochronous traffic pattern properties

Charac	teristics	Notes
Data transmission scheme	periodic	
Data transmission constraints	deadline	End-to-end one-way latency <sup>2</sup> less than 20% (link speeds > 100 Mbit/s) / 50% (link speeds <= 100 Mbit/s) of network cycle
Data period	1μs 1ms	
	250µs4ms	
Data transmission synchronized to network cycle	Yes	
Application synchronized to working clock	Yes	
Acceptable jitter	n.a.	Deadline shall be kept
Acceptable frame loss	0n frames	Media redundancy requirements according to the required tolerance; e.g. seamless redundancy for value 0
Payload	1 IEEE Std 802.3 maximum data payload size (i.e. 1500 bytes)	Data size negotiated during connection establishment

478 479

isochronous domain: All stations, which share a common

480 481 482

- working clock,
- network cycle, and

traffic model (traffic class definition).

483 484

## Requirements on network cycle times:

484 485

1 µs to 1 ms at link speed 1 Gbit/s (or higher)

- 250 µs to 4 ms

at link speed 100 Mbit/s (or lower, e.g. 10 Mbit/s)

#### 486

## 2.4.3.2 Delay requirements

487 488

To make short control loop times feasible PHY, MAC and bridge delays shall meet upper limits:

489

- PHY delays shall meet the upper limits of Table 5.MAC delays shall meet the upper limits of Table 6.
- 490
- Bridge delays shall be independent from the frame size and meet the upper limits of Table 7.

491

Figure 17 shows the definition of PHY delay, MAC delay and Bridge delay reference points.

\_

<sup>&</sup>lt;sup>2</sup> The end-to-end one-way latency is measured from the arrival of the last bit at the ingress edge port of the bridged network to the transmission of the last bit by the egress edge port of the bridged network (see, e.g., Annex L.3 in IEEE Std 802.1Q-2014).

495

Figure 17 - delay measurement reference points

Table 5 - Expected PHY delays

Device	RX delay <sup>C</sup>	TX delay <sup>C</sup>	Jitter
10 Mbit/s	<< 1 µs	<< 1 µs	< 4 ns
100 Mbit/s MII PHY	210 ns (Max. 340 ns) <sup>a</sup>	90 ns (Max. 140 ns) <sup>a</sup>	< 4 ns
100 Mbit/s RGMII PHY	210 ns <sup>b</sup>	90 ns <sup>b</sup>	< 4 ns
1 Gbit/s RGMII PHY	<< 500 ns <sup>b</sup>	<< 500 ns <sup>b</sup>	< 4 ns
2,5 Gbit/s RGMII PHY	<< 500 ns <sup>b</sup>	<< 500 ns <sup>b</sup>	< 4 ns
5 Gbit/s RGMII PHY	<< 500 ns <sup>b</sup>	<< 500 ns <sup>b</sup>	< 4 ns
10 Gbit/s	Tdb	tbd	tbd
25 Gbit/s - 1 Tbit/s	n.a.	n.a.	n.a.

 $<sup>^{\</sup>rm a}$  According IEEE 802.3 for 100 Mbit/s full duplex with exposed MII.

496 497

Table 6 - Expected MAC delays

Link speed	Maximum RX delay	Maximum TX delay
10 Mbit/s	<< 1 µs	<< 1 µs
100 Mbit/s	<< 1 μs	<< 1 μs
1 Gbit/s	<< 1 µs	<< 1 µs

**Use Cases IEC/IEEE 60802** Page 24 of 64

<sup>&</sup>lt;sup>b</sup> Values from 100 Mbit/s PHYs (or better) are needed to allow substitution even for Gigabit or higher.

<sup>&</sup>lt;sup>C</sup> Lower values mean more performance for linear topology.

Link speed	Maximum RX delay	Maximum TX delay
2,5 Gbit/s	<< 1 µs	<< 1 µs
5 Gbit/s	<< 1 µs	<< 1 µs
10 Gbit/s	<< 1 μs	<< 1 μs
25 Gbit/s - 1 Tbit/s	n.a.	n.a.

498 499

Table 7 - Expected Ethernet Bridge delays

Link speed	Value	Comment
10 Mbit/s	< 30 µs	No usage of bridging expected
100 Mbit/s	< 3 µs	Bridge delay measure from MII to MII
1 Gbit/s	< 1 µs	Bridge delay measure from RGMII to RGMII
2,5 Gbit/s	< 1 µs	Bridge delay measure from XGMII to XGMII
5 Gbit/s	< 1 µs	Bridge delay measure from XGMII to XGMII
10 Gbit/s	< 1 µs	Bridge delay measure from XGMII to XGMII
25 Gbit/s – 1 Tbit/s:	n.a.	No covered by this specification

510

511 512

#### 2.4.4 Use case 03: Control Loops with bounded latency

Control loops with bounded latency implement a cyclic traffic pattern for non-isochronous applications, which are not synchronized to the network access (see Table 3).

Figure 18 shows the principle how network cycle, transfer time and application time interact in this use case. The control loop function starts at an application defined time, which is not synchronized to the network access.

513514

515

516

Figure 18 – network cycle and non-isochronous application (Basic model)

Extensions of this model analogous to Figure 9 (multiple applications with differing application lengths) are also possible.

Use Cases IEC/IEEE 60802 Page 25 of 64

## 517 2.4.4.1 Cyclic operation model

519 520 521

Figure 19 - cyclic operation model

## Cyclic operation characteristics:

Multiple applications with different application periods are supported. Applications don't need to be synchronized to working clock, but may be synchronized:

Devices:Controller:

Multiple update times based on different reduction ratios are supported. Network access is synchronized to network cycle (WorkingClock):

Devices: ÖController: Ö

### 522 The single steps of the cyclic operation model are:

1	Controller periodic tasks don't need to be synchronized to working clock, but may be synchronized.
	Periodic task period (t1) != network cycle period (t2).
2	Data transmission is synchronized to network cycle (Working Clock)
3	Device input data must reach controller within a communication monitoring defined deadline (communication protocol).
	Controller application assumes a kept update interval but doesn't know whether it is kept or not.
	Communication disturbances are recognized and signaled asynchronously by communication protocol to application.
	Controller application operates on local process image data. Local process image decouples communication protocol from application.
4	Controller output data transmission is synchronized to network cycle (Working Clock).

Controller output data must reach device within a communication monitoring defined deadline (communication protocol).

Device application assumes an kept update interval but doesn't know whether it is kept or not.

Communication disturbances are recognized and signaled asynchronously by communication protocol to application.

Device application operates on local process image data. Local process image decouples communication protocol from application.

523524

## 2.4.4.2 Cyclic traffic pattern

529

530

531

532

533

Control loops with bounded latency implement a cyclic traffic pattern. More relaxed control reaction time requirements (e.g. 10 ms - 10 s) allow free running applications instead of isochronous applications. In consequence transfer time requirements are more relaxed as well. The transfer time may be longer than the network cycle in this use case.

For a given target transfer time the number of possible bridges on a communication path is restricted due to PHY-, MAC- and bridge-delay contributions, but can be much higher compared to Use case 02: Control Loops with guaranteed low latency.

<u>Cyclic real-time:</u> transfer time may be longer than network cycle and applications are decoupled from the working clock.

534

Table 8 - cyclic traffic pattern properties

Characteristics		Notes
Data transmission scheme	periodic	
Data transmission constraints	deadline	End-to-end one-way latency <sup>3</sup> less than X * network cycle (X   1 n)
Data period	X * network cycle (X   1 n)	
Data transmission synchronized to network cycle	Yes	
Application synchronized to working clock	No	
Acceptable jitter	n.a.	Deadline shall be kept
Acceptable frame loss	0n frames	Media redundancy requirements according to the required tolerance; e.g. seamless redundancy for value 0
Payload	1 IEEE Std 802.3 maximum data payload size (i.e. 1500 bytes)	Data size negotiated during connection establishment

535 536

Cyclic real-time domain: All stations, which share a common

traffic model (traffic class definition).

537

538

Use Cases IEC/IEEE 60802 Page 27 of 64

<sup>&</sup>lt;sup>3</sup> The end-to-end one-way latency is measured from the arrival of the last bit at the ingress edge port of the bridged network to the transmission of the last bit by the egress edge port of the bridged network (see, e.g., Annex L.3 in IEEE Std 802.1Q-2014).

## Requirements:

Stations shall be able to implement Use case 03: Control Loops with bounded latency and Use case 03: Control Loops with bounded latency concurrently.

Transmission paths shall be able to handle different

- · working clocks, and
- network cycles.

561

562563

564

567

## 2.4.5 Use case 04: Reduction ratio of network cycle

Application needs may limit the in principle flexible network cycle time to a defined granularity. E.g. in case of network cycle granularity 31,25 µs the possible network cycles are:

```
>= 1Gbit/s: 31,25 \mus * 2<sup>n</sup> | n=0 .. 5 < 1Gbit/s: 31,25 \mus * 2<sup>n</sup> | n=2 .. 7
```

Application cycle times are the result of the used network cycle times together with reduction ratios:

31,25 µs to 512 ms

<u>Reduction ratio</u>: The value of "reduction ratio" defines the number of network cycles between two consecutive transmits.

<u>Phase</u>: The value of "phase" in conjunction with "reduction ratio" defines the starting network cycle for the consecutive transmits.

Figure 20 – network cycle and application cycle

Examples: see Use case 06: Drives without common application cycle but common network cycle.

Requirements:

566

Useful 802.1 mechanisms:

568 · ...

### 2.4.6 Use case 05: Drives without common application cycle

#### 570 2.4.6.1 Background information

569

573

575

578

579 580

581 582

583

584

590

The cycle time requirements of different vendors may be based on their technology, which cannot 571 572

be changed with reasonable effort. These requirements may be based on hardware dependencies,

independent of the capabilities of the communication part of the device.

574 Figure 21 shows an example, where Vendor A needs to communicate with 31,25 µs between its

devices (A1 with A2), and Vendor B needs to communicate with 50 µs (between B1 and B2).

The communication with the controller which has to coordinate both of them must be a multiple of 576

577 their local cycles. A1 needs to exchange data every 125µs with the Controller, B1 needs to

exchange data every 200µs with the Controller.

Servo drives from different vendors (Vendor A and Vendor B) are working on the same network.

For specific reasons the vendors are limited in the choice of the period for their control loop.

Figure 21 – network with different application cycles

### The following Communication Relations are expected to be possible:

```
585
             Servodrive A1 Bà Servodrive A2: 31,25 µs
586
             Servodrive B1 Bà Servodrive B2: 50 µs
             Controller Bà Servodrive A1: 125 µs
587
             Controller Bà Servodrive B1: 200 µs
588
589
             Servodrive A1 Bà Servodrive B1: 1 ms
```

591 Figure 22 shows a similar use case where all drives are connected in a line and every drive needs 592 direct data exchange to the Controller and additionally to its direct neighbor.

593 Some applications might be more complex where the physical topology does not match the logical order of drives. 594

620

621

624

625

626

627

628

629

630

634

The Controller runs 2 parallel programs in multitasking, one program with 125  $\mu$ s cycle, and another with 200  $\mu$ s cycle. Alternatively there might also be 2 independent controllers on the same network, one of vendor A and one of vendor B.

After every program execution, data needs to be exchanged between Controller and Servodrive.

The time window for this exchange is application specific.

The actual data exchange on the wire can happen at any time in this window, the devices are not dependent on any exact transmission or reception timing, as long as the packet is in the scheduled window.

#### 2.4.7 Use case 06: Drives without common application cycle but common network cycle

The concept of multiple different application cycles which are based on a common network cycle is described in Use case 04: Reduction ratio of network cycle.

Examples with different application cycle times but common network cycle time 31,25 µs:

- 31,25 μs, i.e. reduction ratio 1 for current control loop,
   250 μs, i.e. reduction ratio 4 for position control loop,
   1 ms, i.e. reduction ratio 16 for motor speed control loop,
  - 16 ms, i.e. reduction ratio 256 for remote IO.

Figure 25 - different application cycles but common network cycle

655 656

657

658

659

660

Figure 26 - ring topology

When a production cell is also arranged in a ring topology the resulting architecture of cell with attached machines is a connection of rings.

To even improve availability of the connection from the production cell into the machines this link can be arranged redundantly as well (machine 1 in Figure 27):

Figure 27 – connection of rings

651 Requirement:

Support redundant topologies with rings.

Useful 802.1 mechanisms:

· ...

2.5.2 Use case 08: High Availability

High availability systems are composed of:

- Redundant networks, and
- Redundant stations.

Use Cases IEC/IEEE 60802 Page 33 of 64

E.g. tunnel control: 661

662 Tunnels need to be controlled by systems supporting high availability because airflow and fire 663 protection are crucial for the protection of people's lives. In this case PLC, remote IO and network 664

are installed to support availability in case of failure.

Figure 28 – example topology for tunnel control

667 Requirement:

Failure shall not create process disturbance – e.g. keep air flow active / fire control active.

The number of concurrent active failures without process disturbance depends on the application requirements and shall not be restricted by TSN profile definitions.

Parameter, program, topology changes need to be supported without disturbance.

Useful 802.1Q mechanisms:

- Redundancy for PLCs, Remote IOs and paths through the network
- 675

677 Further high availability control applications:

- 678 Ship control
- 679 Power generation
- Power distribution 680

749

750

751

752

753

740

742

743

### Useful 802.1Q mechanisms:

- · Priority Regeneration,
- separate "brownfield traffic queue".
- · Queue-based resource allocation.

### 2.5.7 Use case 13: Mixed link speeds

Industrial use cases refer to link speeds, as shown in Table 9, in the range from 10 Mbit/s to 10 GBit/s for Ethernet and additional Wi-Fi, Bluetooth and 5G. Thus, the TSN domains need to handle areas with different link speeds.

Table 9 - Link speeds

Link speed	Media	Comments
100 kbit/s - 3 Mbit/s	Radio Bluetooth	These devices are connected thru a Bluetooth access point. They may be battery powered.
1 Mbit/s – 1 Gbit/s	Radio Wi-Fi	These devices are connected thru a Wi-Fi access point. They may be battery powered.
1 Mbit/s - 10 Gbit/s (theoretical/expected)	Radio 5G	These devices are connected thru a 5G access point. They may be battery powered.

Link speed	Media	Comments
		May be used for end station "only" devices connected as leafs to the domain.
10 Mbit/s	Copper or fiber	Dedicated to low performance and lowest energy devices for e.g. process automation.
		These devices may use PoE as power supply.
100 MBit/s	Conner or fiber	Historical mainly used for Remote IO and PLCs.
TOO WIDIL/S	Copper or fiber	Expected to be replaced by 1 GBit/s as common link speed.
1 GBit/s	Copper or fiber	Main used link speed for all kind of devices
2,5 GBit/s	Copper or fiber	High performance devices or backbone usage
5 GBit/s	Copper or fiber	Backbone usage, mainly for network components
10 GBit/s	Fiber	Backbone usage, mainly for network components
25 GBit/s - 1 Tbit/s	tbd	Backbone usage, mainly for network components

756

757

758

759

762

763

764

Mixing devices with different link speeds is a non-trivial task. Figure 35 and Figure 36 show the calculation model for the communication between an IOC and an IOD connected with different link speeds.

The available bandwidth on a communication path is determined by the path segment with the minimum link speed.

The weakest link of the path defines the usable bandwidth. If the topology guideline ensures that the connection to the end-station always is the weakest link, only these links need to be checked for the usable bandwidth.

Figure 35 - mixed link speeds

Figure 36 - mixed link speeds without topology guideline

765

766

767

## 769 Requirement:

Links with different link speeds as shown in Figure 35 share the same TSN-IA profile based communication system at the same time.

Links with different link speeds without topology guideline (Figure 36) may be supported.

772 773 774

### Useful 802.1 mechanisms:

775

776 777

778

779

780

781

2.5.8 Use case 14: Multiple isochronous domains

Figure 37 shows a machine which needs due to timing constraints (network cycle time together with required topology) two or more separated isochronous real-time domains but shares a common cyclic real-time domain.

Both isochronous domains may have their own Working Clock and network cycle. The PLCs need to share remote IOs using cyclic real-time traffic.

Figure 37 - multiple isochronous domains

Some kind of coupling (e.g. shared synchronization) between the isochronous domains / Working Clocks may be used (see Figure 38).

All isochronous domains may have different network cycle times, but the cyclic real-time data exchange shall still be possible for PLCs from both isochronous domains.

782

783 784

Figure 38 - multiple isochronous domains - coupled

### Requirements:

All isochronous real-time domains may run independently, loosely coupled or tightly coupled. They shall be able to share a cyclic real-time domain.

### Useful 802.1 mechanisms:

- separate "isochronous" and "cyclic" traffic queues,
- · Queue-based resource allocation in all bridges,
- · ...

### 2.5.9 Use case 15: Auto domain protection

Machines are built in a way that not always all devices are really attached either due to different machine models/variants or repair. In this use case a TSN domain shall not expand automatically when e.g. two machines get connected via an unplanned and unintended link.

Figure 39 - auto domain protection

### Requirement:

Support of auto domain protection to prevent unintended use of traffic classes

### 2.5.11.2 **A** representative example for data flow requirements

TSN domains in an industrial automation network for cyclic real-time traffic can span multiple Cyber-physical systems, which are connected by bridges. The following maximum quantities apply:

- Stations: 1024
- Network diameter: 64
- 976 per PLC for Controller-to-Device (C2D) one to one or one to many communication:
  - 512 producer and 512 consumer data flows
    - 64 kByte Output und 64 kByte Input data

- V1.0 2018-07-20 per Device for Device-to-Device (D2D) – one to one or one to many – communication: 879 088 o 2 producer and 2 consumer data flows 881 o 1400 Byte per data flow 882 per PLC for Controller-to-Controller (C2C) – one to one or one to many – communication: 883 o 64 producer and 64 consumer data flows 884 1400 Byte per data flow 885 Example calculation for eight PLCs  $\rightarrow$  8 x 512 x 2 = 8192 data flows for C2D communication 886  $\rightarrow$  8 x 64 x 2 = 1024 data flows for C2C communication 887 888 → 8 x 64 kByte x 2 = 1024 kByte data for C2D communication 889  $\rightarrow$  8 x 64 x 1400 Byte x 2 = 1400 kByte data for C2C communication 890 All above shown data flows may optionally be redundant for seamless switchover due to the 891 need for High Availability. 892 893 Application cycle times for the 512 producer and 512 consumer data flows differ and follow the 894 application process requirements. E.g. 125 µs for those used for control loops and 500 µs to 512 ms for other application processes. 895 896 All may be used concurrently and may have frames sizes between 1 and 1440 bytes. 897 2.5.11.3 A representative example of communication use cases 898 IO Station – Controller (input direction) 899 Up to 2000 published + subscribed signals (typically 100 – 500) 900 Scan interval time: 0,5 .. 100ms (typical 10ms) 901 Controller – Controller (inter-application) 902 Up to 1000 published + subscribed signals (typically 100 – 250) 903 Application task interval time: 10..1000ms (typical 100ms) 904 - Resulting Scan interval time: 5 ... 500 ms 905 Closing the loop within/across the controller 906 Up to 2000 published + subscribed signals (typically 100 – 500) 907 Application task interval time: 1..1000ms (typical 100ms)
- 908 Resulting Scan interval time when spreading over controllers: 0,5 ... 500 ms
- 909 Controller – IO Station (output direction)
- 910 Up to 2000 published + subscribed signals (typically 100 – 500)
- 911 Application task interval time: 10..1000ms (typical 100ms
- 912 Resulting Scan interval time: 5 ... 500 ms 913
- 2.5.11.4 "Fast" process applications 914
- 915 The structure shown in Figure 1 applies. Figure 41 provides a logic station view.

- Mix of different device types from different vendors
- Many changes during runtime

969 970

971 972

2.5.12 Bridge Resources 973

The bridge shall provide and organize its resources in a way to ensure robustness for the traffic defined in this document as shown in Formula (1).

The queuing of frames needs resources to store them at the destination port. These resources may be organized either bridge globally, port globally or queue locally.

The chosen resource organization model influences the needed amount of frame resources.

977 978

974

975

976

For bridge memory calculation Formula (1) applies.

MinimumFrameMemory = (NumberOfPorts - 1) x MaxPortBlockingTime x Linkspeed (1)

Where

MinimumFrameMemory

is minimum amount of frame buffer needed to avoid frame loss from non stream traffic due to streams blocking egress ports.

NumberOfPorts is number of ports of the bridge without the management port.

is intended maximum blocking time of ports due to streams per **MaxPortBlockingTime** millisecond.

Linkspeed is intended link speed of the ports.

979 980 981

982

Formula (1) assumes that all ports use the same link speed and a bridge global frame resource management. Table 13, Table 14, Table 15, and Table 16 shows the resulting values for different link speeds.

**Use Cases IEC/IEEE 60802** Page 48 of 64

983 984 985

The traffic from the management port to the network needs a fair share of the bridge resources to ensure the required injection performance into the network. This memory (use for the real-time frames) is not covered by this calculation.

986

Table 13 – MinimumFrameMemory for 100 Mbit/s (50%@1 ms)

# of ports	MinimumFrameMemory [KBytes]	Comment
1	0	The memory at the management port is not covered by Formula (1)
2	6,25	All frames received during the 50%@1 ms := 500 µs at one port needed to be forwarded to the other port are stored during the allocation of this port due to stream transmission.
3	12,5	All frames received during the 50%@1 ms := 500 µs at two ports needed to be forwarded to the other port are stored during the allocation of this port due to stream transmission.
4	18,75	All frames received during the 50%@1 ms := 500 µs at three ports needed to be forwarded to the other port are stored during the allocation of this port due to stream transmission.

993 994

995 996 997

997 998 999

1000 1001

10021003

1004 1005 1006 A per port frame resource management leads to the same values, but reduces the flexibility to use free frame resources for other ports.

A per queue per port frame resource management would increase (multiplied by the number of to be covered queues) the needed amount of frame resources dramatically almost without any benefit.

Example "per port frame resource":

100 Mbit/s, 2 Ports, and 6 queue

Needed memory := 6,25 KOctets \* 6 := 37,5 KOctets.

No one is able to define which queue is needed during the "stream port blocking" period.

Bridged End-Stations need to ensure that their local injected traffic does not overload the local bridge resources. Local network access must conform to the TSN-IA profile defined model with management defined limits and cycle times (see e.g. row Data period in Table 4).

## 2.6 Industrial automation machines, production cells, production lines

### 2.6.1 Use case 17: Machine to Machine/Controller to Controller (M2M/C2C) Communication

Preconfigured machines with their own TSN domains, which include tested and approved internal communication, communicate with other preconfigured machines with their own TSN domains, with a supervisory PLC of the production cell (with its own TSN domain) or line (with its own TSN domain) or with an OS (Operator System) (with its own TSN domain).

Figure 45 - M2M/C2C between TSN domains

Figure 45 shows that multiple overlapping TSN Domains arise, when controllers use a single interface for the M2M communication with controllers of the cell, line, plant or other machines. Decoupling of the machine internal TSN Domain can be accomplished by applying a separate controller interface for M2M communication.

- Machine 1: the controller link to its connected cell bridge B1 is concurrently member of the TSN Domains of Machine 1, Production Cell 1, Production Line and Plant.
- Machine 2: the controller link to its connected cell bridge B2 is concurrently member of the TSN Domains of Machine 2, Production Cell 1 and Plant.
- Machine 3: the controller is directly attached to the PLC of Production Cell 2 and is therefore member of the TSN Domain of Production Cell 2. The machine internal TSN Domain is decoupled from M2M traffic by a separate interface.
- Machine 4: the controller link to its connected cell bridge B3 is concurrently member of the TSN Domains of Production Cell 2 and Plant. The machine internal TSN Domain is decoupled from M2M traffic by a separate interface.

Examples:

Use Cases IEC/IEEE 60802 Page 51 of 64

Figure 46 - M2M with supervisory PLC

1032

1033

1034

Figure 46 gives an example of M2M communication to a supervisory PLC.

Figure 47 shows an example of M2M communication relations between four machines.

PLCs with one single interface lead to overlapping communication paths of M2M and machine internal traffic. In this case two TSN domains (Machine / Production cell) need to share resources due to two overlapping TSN domains.

Additionally Figure 48 shows an example where M2M communication is used to connect a PC for diagnostics/monitoring.

Figure 47 - M2M with four machines

Figure 48 - M2M with diagnostics/monitoring PC

Figure 48 shows a M2M diagnostics related use case: communication is cyclic and must happen within short application cycle times. An example of this use case is the verification of proper behavior of a follower drive, in a master-follower application. Today, the use case is covered by

Use Cases IEC/IEEE 60802 Page 52 of 64

1035 connecting a common PC to an interface of the follower drive. The various TSN mechanisms may now make it possible to connect such a PC network interface card anywhere in the system network

and still gather the same diagnostics with the same guarantees, as the current direct connection.

- 1038 The required guarantees are:
- each 4 ms a frame must be sent from a follower drive and have its delivery guaranteed to the
- network interface of the PC used to perform the diagnostics. Of course, local PC-level processing
- of such frames has to be implemented such that the diagnostic application gets the required quality
- 1042 of service.

1037

- From the communication point of view the two types of machine interface shown in Figure 47 are
- identical. The PLC represents the machine interface and uses either a dedicated (machine 1 and 4)
- or a shared interface (machine 2 and 3) for communication with other machines and/or a
- 1046 supervisor PLC.
- The communication relations between machines may or may not include or make use of a
- supervisory PLC.
- 1049 Requirement:
- 1050 <u>All</u> machine internal communication (stream traffic <u>and</u> non-stream traffic) is decoupled from and
- protected against the additional M2M traffic and vice versa.
- 1052 1:1 and 1:many communication relations shall be possible.
- 1053

### 1054 Useful 802 mechanisms:

- 802.1Qbu, 802.1Qbv, 802.1Qci, Fixed priority, 802.3br
- · Priority Regeneration,
- · Queue-based resource allocation,
- · VLANs to separate TSN domains.

### 2.6.2 Use case 18: Pass-through Traffic

Machines are supplied by machine builders to production cell/line builders in tested and approved quality. At specific boundary ports standard devices (e.g. barcode reader) can be attached to the machines. The machines support transport of non-stream traffic through the tested/approved machine ("pass-through traffic") without influencing the operational behavior of the machine, e.g. connection of a printer or barcode reader. Figure 49, Figure 50 and Figure 51 give some examples of pass-through traffic installations in industrial automation.

Figure 49 - pass-through one machine

Figure 50 – pass-through one machine and

Figure 51 - pass-through two machines

Figure 52 - machine with diagnostics / monitoring PC

### Requirement:

<u>All</u> machine internal communication (stream traffic <u>and</u> non-stream traffic) is decoupled from and protected against the additional "pass-through" traffic.

"Pass-through" traffic is treated as separate traffic pattern.

### Useful 802.1Q mechanisms:

- Priority Regeneration,
- separate "pass-through traffic queue",
- Queue-based resource allocation in all bridges,
- Ingress rate limiting.

### 2.6.3 Use case 19: Modular machine assembly

In this use case machines are variable assemblies of multiple different modules. Effective assembly of a machine is executed in the plant dependent on the current stage of production, e.g. bread-machine with the modules: base module, 'Kaisersemmel' module, 'Rosensemmel' module, sesame caster, poppy-seed caster, baking oven OR advertisement feeder for newspapars.

Figure 53 may have relaxed latency requirements, but the machine in Figure 54 needs to work with very high speed and thus has very demanding latency requirements.

1098

1099

1100

Figure 54 - modular advertisement feeder

### Requirement:

Modules can be assembled to a working machine variably on-site (either in run, stop or power down mode) as necessary (several times throughout a day). The machine produces the selected variety of a product. Communication relying on TSN features is established automatically after the modules are plugged without management/ configuration interaction.

### 2.6.4 Use case 20: Tool changer

Tools (e.g. different robot arms) are in power off mode. During production a robot changes its arms for different production steps.

They get mechanically connected to a robot arm and then powered on. The time till operate influences the efficiency of the robot and thus the production capacity of the plant. Robots may

**Use Cases IEC/IEEE 60802** Page 55 of 64 share a common tool pool. Thus the "tools" are connected to different robots during different production steps.

Figure 55 - tool changer

1104 1105 1106

1107

11081109

1110

1111

1103

### Requirement:

- Added portion of the network needs to be up and running (power on to operate) in less than 500ms.
- Extending and removing portions of the network (up to 16 devices) in operation
  - by one connection point (one robot using a tool)
  - o by multiple connection points (multiple robots using a tool)

11121113

1114

1115

### Useful 802.1Q mechanisms:

- preconfigured streams
- 1116 · ..
- 1117 2.6.5 Use case 21: Dynamic plugging and unplugging of machines (subnets)

E.g. multiple AGVs (automatic guided vehicles) access various docking stations to get access to the supervisory PLC. Thus, an AGV is temporary not available. An AGV may act as CPS or as a bunch of devices.

Figure 56 - AGV plug and unplug

11221123

### 1124 Requirement:

- The traffic relying on TSN features from/to AGVs is established/removed automatically after plug/unplug events.
- 1127 Different AGVs may demand different traffic layouts.

- The time till operate influences the efficiency of the plant. 1128
- Thousands of AGS may be used concurrently, but only a defined amount of AGVs is connected at 1129 a given time. 1130

1131

1132

1134

1133

## Useful 802.1Q mechanisms:

- preconfigured streams
- 1135

1136

1137

1138

1141

### 2.6.6 Use case 22: Energy Saving

1139 Complete or partial plant components are switched off and on as necessary to save energy. Thus, portions of the plant are temporarily not available. 1140

1142

Figure 57 - energy saving

### 1143 Requirement:

- Energy saving region switch off/on shall not create process disturbance. 1144
- 1145 Communication paths through the energy saving area between end-stations, which do not belong to the energy saving area, shall be avoided. 1146

1147 1148 1149

1150

### Useful 802.1Q mechanisms:

Appropriate path computation by sorting streams to avoid streams passing through energy saving region.

### 1151 2.6.7 Use case 23: Add machine, production cell or production line

- When production capacity is exhausted, additional machines, production cells or even production 1152 lines are bought and integrated into a plant. 1153
- 1154 E.g. an additional welding robot is added to a production cell to increase production capacity. The
- additional machine has to be integrated into the production cell control with minimal disturbance of 1155
- 1156 the production cell process.

1158

1160

1161 1162

1157

Figure 58 - add machine

1159 Requirement:

Adding a machine/cell/production line shall not disturb existing installations

<u>Useful mechanisms:</u>

1163 • ...

1164

1165

1167

2.6.8 Use case 24: Multiple applications in **a** station using the TSN-IA profile

1166 E.g. Technology A and B in PLC and devices.

Figure 59 – two applications

1169

1168

1170 Requirement:

Stations with multiple applications using TSN traffic classes shall be supported.

1172 1173

Useful 802.1 mechanisms:

1174 . .

. . . .

1175 2.6.9 Use case 25: Functional safety

1176 Functional safety is defined in IEC 61508 as "part of the overall safety relating to the EUC

1177 [Equipment Under Control] and the EUC control system that depends on the correct functioning of

Use Cases IEC/IEEE 60802 Page 58 of 64

the E/E/PE [electrical/electronic/programmable electronic] safety-related systems and other risk 1178 1179 reduction measures"

1180

1181 IEC 61784-3-3 defines a safety communication layer structure, which is performed by a standard transmission system (black channel), and an additional safety transmission protocol on 1182

top of this standard transmission system.

1183 1184 1185

The standard transmission system includes the entire hardware of the transmission system and the related protocol functions (i.e. OSI layers 1, 2 and 7).

1186 1187 1188

Safety applications and standard applications are sharing the same standard communication systems at the same time.

1190

1189

Figure 60 - Functional safety with cyclic real-time

1192 1193

1191

### Requirement:

1194 Safety applications (as black channel) and standard applications share the same TSN-IA profile 1195 based communication system at the same time.

1196 1197

### Useful 802.1 mechanisms:

1198

# 2.7 DCS Reconfiguration

# 1199 1200

2.7.1 Challenges of DCS Reconfiguration Use Cases The challenge these use cases bring is the influence of reconfiguration on the existing

1202 communication: all has to happen without disturbances to the production!

1203 We consider important the use case that we can connect any number of new devices wherever in 1204 the system and they get connectivity over the existing infrastructure supporting TSN features 1205 without a change to the operational mode of the system.

1206

1207

1208

1209

1201

### 2.7.2 Use case 26: DCS Device level reconfiguration

The structure shown in Figure 1 applies. Figure 61 provides a logic station view.

- SW modifications to a device
- 1210 A change to the device's SW/SW application shall happen, which does not require changes 1211 to the SW/SW application running on other devices (incl. firmware update): add examples
- 1212 Device Exchange/Replacement

The process device is replaced by another unit for maintenance reason, e.g. for off-process calibration or because of the device being defective (note: a "defective device may still be fully and properly engaged in the network and the communication, e.g. if just the sensor is not working properly anymore):

1217 - Use case: repair

1248

- 1218 · Add/remove additional device(s)
  - A new device is brought to an existing system or functionality, which shall be used in the application, is added to a running device, e.g. by enabling a SW function or plugging in a new HW-module. Even though the scope of change is not limited to a single device because also the other device engaged in the same application
  - For process devices, servers: BIOS, OS and applications updates, new VMs, workstations
  - Use cases: replacement with upgrade/downgrade of an existing device, simply adding new devices, removal of device, adding connections between devices
  - Influencing factors relative to communication
    - Communication requirements of newly added devices (in case of adding)
    - Existing QoS parameters (i.e. protocol-specific parameters like TimeOuts or Retries)
    - Device Redundancy
    - Network/Media Redundancy
- 1231 Virtualization
  - For servers: in-premise or cloud
- 1233 Clock types in the involved process devices
- 1234 Universal time and working clock domains
- 1235 Cycle time(s) needed by new devices
- 1236 Available bandwidth
- 1237 Existing security policies

Figure 61 – Device level reconfiguration use cases

### 1240 2.7.3 Use case 27: DSC System level reconfiguration

1241 The structure shown in Figure 1 applies. Figure 62 provides a logic station view.

- Extend an existing plant
  - Add new network segment to existing network
    - Existing non-TSN / Newly added is TSN
    - Existing TSN / Newly added is TSN
- 1246 · Update the system security policy
  - [New key lengths, new security zones, new security policy]
  - To be defined how and by whom to be handled
- 1249 · Influencing factors

Same as for "device-level"

Figure 62 - System level reconfiguration use cases

### 2.8 Further Industrial Automation Use Cases

### 2.8.1 Use case 28: Network monitoring and diagnostics

Diagnostics plays an important role in the management of systems and of devices. Generally speaking the mechanisms used in this context are acyclic or having large cycle times so that they could perhaps be considered, from a networking perspective as sporadic. Most of the use cases related to diagnostics will be included in this category.

- Quick identification of error locations is important to minimize downtimes in production.
- Monitoring network performance is a means to anticipate problems so that arrangements can be planned and put into practice even before errors and downtimes occur.
- Identification of devices on an industrial Ethernet network must be done in a common, interoperable manner for interoperability on a converged TSN network. This identification both needs to show the type of device, and the topology of the network. IEEE 802.1AB, the Link Layer Discovery Protocol (LLDP), provides one possible mechanism for this to be done at layer two, but provides a large degree of variability in implementation.

1267

### Requirement:

- 1269 Minimize downtime
- Monitoring and diagnostics data including used TSN features shall be provided, e.g. established streams, failed streams, stream classes, bandwidth consumption, ...
  - A discovery protocol such as IEEE 802.1AB shall be leveraged to meet the needs of TSN-IA.

1273 1274 1275

1272

## Useful 802.1 (ietf) mechanisms:

- MIBs (SNMP)
- YANG (NETCONF/RESTCONF)

1277 1278

1279

1280

1282

1283

1284

1276

## 2.8.2 Use case 29: Security

- Industrial automation equipment can become the objective of sabotage or spying.
- 1281 Therefore all aspects of information security can be found in industrial automation as well:
  - <u>Confidentiality</u> "is the property, that information is not made available or disclosed to unauthorized individuals, entities, or processes."
  - Integrity means maintaining and assuring the accuracy and completeness of data.

1285 • Availability implies that all resources and functional units are available and functioning correctly when they are needed. Availability includes protection against denial-of-service attacks.

Authenticity aims at the verifiability and reliability of data sources and sinks.

1289 1290

1288

### Requirement:

- Optional support of confidentiality, integrity, availability and authenticity.
- Security shall not limit real-time communication

1293 1294

Protection against rogue applications running on authenticated stations are out of scope.

1295 1296

### Useful mechanisms:

- 1297 · 802.1X
- 1298 · IEC62443
- 1299 .

1300 1301

### 2.8.3 Use case 30: Firmware update

Firmware update is done during normal operation to make sure that the machine e.g. with 1000 devices is able be updated with almost no down time.

1302 1303 1304

With bump: separate loading (space for 2 FW versions required) and coordinated activation to minimize downtime

1305 1306 1307

Bumpless: redundant stations with bumpless switchover – the single device may lose connection (bump)

1308 1309 1310

### Requirement:

1311 Stations shall be capable to accept and store an additional fw version without disturbance.

312

### Useful 802.1 mechanisms:

1314

1315

1316

2.8.4 Use case 31: Virtualization Workload consolidation is done by virtualizing the hardware interfaces. Even in such kind of environment the TSN features according to the TSN-IA profile shall be available and working.

1317 1318

### vSwitch / vBridge

1319 1320

Figure 63 and Figure 64 show the two principle setups for an Ethernet communication concept allowing both, communication VM to Ethernet and VM to VM. The applications inside the VM shall not see, whether they communicate to another VM or an Ethernet node.

1324

1325

Figure 63 - Ethernet interconnect with VM based vBridge

1326 1327

1328

1329

Figure 63 scales for an almost infinite amount of VMs, because the memory bandwidth and the compute power of the vMAC/vPort and vSwitch/vBridge VM are much higher than the PCle bandwidth to the NIC.

1330

Figure 64 – Ethernet interconnect with PCIe connected Bridge

1332 1333

1331

Figure 64 fits for a limited amount of VMs, because it saves the additional vSwitch/vBridge VM. For a given amount of VMs, e.g. Gen3 x4 or Gen4 x4, seems to be sufficient.

1334 1335 1336

### Requirement:

- vBridge and vPort should behave as real Bridge and real Port: data plane, control plane, ...
- 1338 vBridge and vPort can become members of TSN domains.
- 1339 Should work like use case "multiple applications"

1341 Useful 802.1 mechanisms:

1342 1343

1344 2.8.5 Use case 32: Digital twin

1345 1346

Virtual pre-commissioning of machines can save a lot of time and money.

1347 Up to 30 % time-saving in the development of new machines are foreseen by an increased 1348

engineering efficiency due to the implementation and usage of digital twins.

1349 Faster development, delivery and commissioning of new machines at customer locations should be

1350 possible.

1351 A digital twin shows the real machine in as much detail as possible and allows simulation of its operation. With the help of digital twins machines can gradually and virtually be developed – in 1352 1353 parallel to the real production and commissioning process of the machines at customer locations.

1354 1355

### Requirement:

Reliable planning, development, testing, simulation and optimization results shall be possible

1356 1357 1358

1360

1361

1362 1363

1364

### Useful 802.1 mechanisms:

1359

2.8.6 Use case 33: Device replacement without engineering

Any device in a plant, i.e. end-station, bridged end-station or bridge, may get broken eventually. If this happens fast and simple replacement of a broken device is necessary to keep production disturbance at a minimum (see also: 2.7.2 Use case 26: DCS Device level reconfiguration). Support of "mechanical" replacement of a failed device with a new one without any engineering effort (i.e. without the need for an engineering tool) is a prerequisite for minimal repair downtime.

1365 1366 1367

### Requirement:

In case of repair it shall be possible to replace end-stations, bridged end-stations or brides without the need of an engineering tool.

1369 1370 1371

1368

### Useful 802.1 mechanisms:
