Venue:

IEEE 802.16 Session #46, Dallas, TX U.S.A., November 2006 (Relay Task Group)

Base Document:

IEEE C802.16j-06/202, URL: <http://relay.wirelessman.org>

Purpose:

To propose throughput metrics for end-to-end QoS management

Notice:

This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.

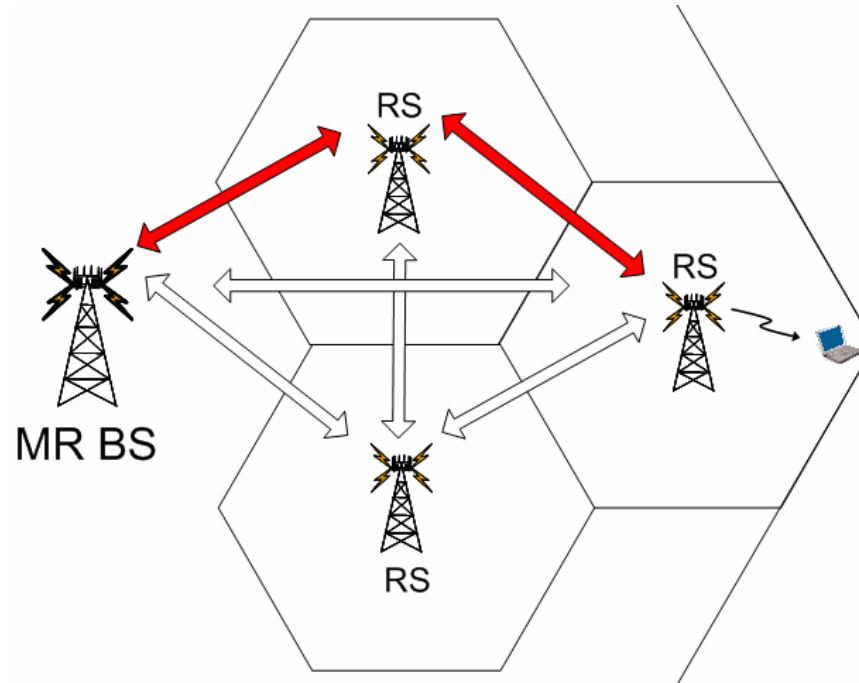

Release:

The contributor grants a free, irrevocable license to the IEEE to incorporate material contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.

IEEE 802.16 Patent Policy:

The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures <http://ieee802.org/16/ipr/patents/policy.html>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, provided the IEEE receives assurance from the patent holder or applicant with respect to patents essential for compliance with both mandatory and optional portions of the standard." Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <mailto:chair@wirelessman.org> as early as possible, in written or electronic form, if patented technology (or technology under patent application) might be incorporated into a draft standard being developed within the IEEE 802.16 Working Group. The Chair will disclose this notification via the IEEE 802.16 web site <http://ieee802.org/16/ipr/patents/notices>.

End-to-End Link Quality Tracking

- MR BS needs to keep track of link qualities (end-to-end QoS) over multi-hop routes – these depend on physical channel conditions over different hops (OFDMA PHY)
- **Goal:** Design PHY abstraction metrics to minimize feedback overhead complexity

Summary of Contribution

- Propose a methodology to estimate end-to-end quality of a multi-hop communication link at the MMR BS:
- Quality of Service (QoS) Metrics
 - => Mean end-to-end throughput
 - => Mean end-to-end delay
- **Approach 1:** Compute the harmonic mean of the capacities (only depends on SINR) over individual wireless links.
- **Approach 2:** Compute the harmonic mean of achievable throughputs (accounting for link errors, finite MCSs, overheads etc.) over individual wireless links may be computed.
- The second approach is also equivalent to the summation of the expected transmission time (ETT) over each hop.

End-to-End PHY Abstraction for a Multi-hop Route

- An **end-to-end throughput metric** can be mapped to each established multi-hop route; which can be calculated as:

$$End_to_End_Throughput = \left(\sum_{n=1}^N \frac{1}{Per_Link_Throughput_over_Hop_n} \right)^{-1}$$

- This formula assumes orthogonal resource sharing (in time or frequency) among hops in a given routing path.
- **Benefit 1:** Such a PHY abstraction metric informs MMR BS about the overall quality of the multi-hop route in an end-to-end sense and allows for quick decision making, e.g. establish a new route if the link quality falls below the desired end-to-end QoS level.
- **Benefit 2:** Several centralized functionalities coordinated by MMR BS (e.g. scheduling algorithms, routing algorithms, latency management, other MAC and higher layer functions) can utilize from this end-to-end PHY abstraction metric.
- **Any per-link PHY abstraction metric can be used** on each hop to store PER vs. SINR tables (e.g. mean capacity, EESM etc.)

Possible Per-Link PHY Abstractions

- PHY abstractions enable to reduce the vector of SNR values to a small set of parameters, which can be used to approximate link layer performance.
- Mean-capacity (proposed for 802.11)

$$\log_2(1 + SINR_{eff,n}) = \frac{1}{K} \sum_{k=1}^K \log_2(1 + SINR_{n,k})$$

$$\Rightarrow SINR_{eff,n} = 2^{\frac{1}{K} \sum_{k=1}^K \log_2(1 + SINR_{n,k})} - 1$$

- Exponential effective SINR mapping (EESM) (proposed for 3G)

$$SINR_{eff,n} = -\beta \log \left(\frac{1}{K} \sum_{k=1}^K \exp \left(-\frac{SINR_{n,k}}{\beta} \right) \right)$$

Capacity-based End-to-End PHY Abstraction

$$C = \frac{1}{\sum_{n=1}^N \frac{1}{C_n}} = \frac{1}{\sum_{n=1}^N \frac{1}{\log_2(1 + SINR_{eff,n})}}$$

C \Rightarrow End-to-end capacity

C_n \Rightarrow Effective capacity over hop $n=1, \dots, N$

$SINR_{eff,n}$ \Rightarrow Effective SINR over hop n (can be computed using any PHY abstraction; e.g. mean capacity, EESM etc.)

N \Rightarrow Number of hops over the established route between BS and SS

Throughput-based End-to-End PHY Abstraction

- ETT is a metric used for routing in 802.11s mesh standard.
- For a packet of B bits, end-to-end latency T and end-to-end throughput R are related to each other:

$$\text{Throughput} = \frac{B}{T} = \frac{B}{\sum_{n=1}^N \text{ETT}_n}$$

- Formula for cost per link:

$$\text{ETT}_n = \left[T_{\text{ovrhd}} + \frac{B}{R_n} \right] \text{ETX}_n$$

ETX_n : Expected number of packet transmissions until successful reception over hop subject to instantaneous channel conditions (accounting for HARQ)

R_n : Aggregate data rate per packet over hop based on the MCS chosen by the link adaptation algorithm while satisfying a certain target packet error rate (PER) subject to instantaneous channel conditions

B : Number of bits per packet

T_{ovrhd} : Latency cost per link due to fixed channel access and protocol overheads
