1. Introduction

Traditionally when it is in the development of Internet traffic model it is usually based on the assumption that the Internet traffic flow arrives according to a memory-less Poisson process, which results in the traffic exhibiting the short-term or short range autocorrelation. However, lately it drew people's attention and one found that the aggregated Internet traffic model depicts the long-term autocorrelation, i.e. the autocorrelation function of the traffic remains significant for all lags and it is identified as Self-Similar Process [6]. These Internet traffics statistical distributions can be identified by either Cauchy, or Pareto or Weibull distribution [6]. In this report we will review the characteristics of Email traffic among various Internet traffics and to develop an appropriate Email traffic model identified from these characteristics. In the literature it has not too many references discussing Email traffic. In [2] and [3] they provided the distribution of the Email size, and it is noted that the 90%-tile Email size varies from 80 Kbytes in the model [4] to 250 Kbytes in [3]. And also in [4] it found that Email size can be approximated by a Cauchy distribution function with $\alpha = 0.8$ and $\beta = 1.0$. In the following some general statistics about Email usages are listed or tabulated from the survey conducted at Carnegie Mellon University containing over 1100 Email addresses [1]. The Email traffic model will then be discussed in sequel.

2. Basic Email Statistics

The general statistics about email usage in the survey is tabulated in Table 1 [1]. On the average every respondent sent 14 messages per day, read 30 of them and kept over 1300 in their inboxes.

Table 1 General Email Usage Characteristics

Message	Mean (Standard Deviation)	Median (Out of N=121)
Message read per day	30 (17)	25
Message sent per day	14 (12)	13
Number of inbox Message	1336 (2785)	105
Number of Email folders	22 912)	25
Times checking Email per day	19 (11)	13

3. Message Level Data

The distribution of messages among the various content types is summarized in Table 2. It is to be noted that it is possible for one message containing one more type. The highest percentage of the message content is to ask for action (34%)

Table 2 Distribution of Message Content Types
(one message may contain more than one type)

Message Content	Percentage
Action request	34
Information request	18
Information Attachment	36
Status update	21
Scheduling	14
Reminder	16
Social	8
Other	12

4. Actions on a message

Two possible actions are considered for people taking on a message, namely the *location action* and *reply action*. In the *location action,* it decides people's action on a message to file, delete, or leave the message after processing it. In the reply action, it considers user's response to a message, the user had already replied to, planned to reply, or did not plan to reply a message. The detailed breakdown of the distribution of messages by reply and location actions can be referred to Figure 1.

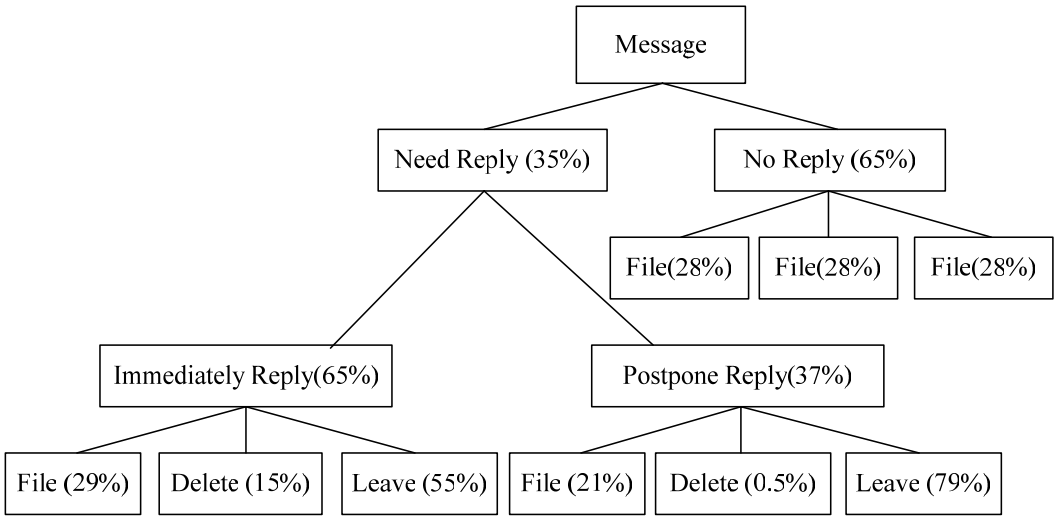

Figure 1 Distribution of Messages by *Reply* and *Location* Actions
(Categories are Mutually Exclusive)

5. Email Protocol

The mostly used Email protocols are POP3 and MAPI (Messaging Application Programming Interface) which is supported by Microsoft Outlook and Exchange Server. The MAPI protocol is in the application layer. In the Outlook, each E-mail involves eleven active TCP connections during Email invoking phase, and each Email transaction consists of multiple MAPI segment transactions in series and each MAPI segment is again segmented into smaller segments. The maximum MAPI segment is 16896 bytes and this information is indicated in the first package of a MAPI segment. Outlook finishes the MAPI segment with ACK acknowledgement transmission, while the Exchange server waits for the MAPI segment completion indication packet before sending the next one. The last packet in the MAPI segment set the "PUSH" bit in the TCP packet to transmit all of the packets in the TCP buffer to the application layer at the receiver side [5].

6. Email Model

The Email traffic has the burst profile as other Internet traffics, and it is characterized by ON/OFF states. In the ON-state Email traffics are transmitted and in the Off-state it is in the idle period. When the duration of the ON-state is short compared with the ON-OFF session length, then other new Email traffics (sub-sessions) are read and the elapse time between Emails sub-session read is randomly distributed as shown in Figure 2.

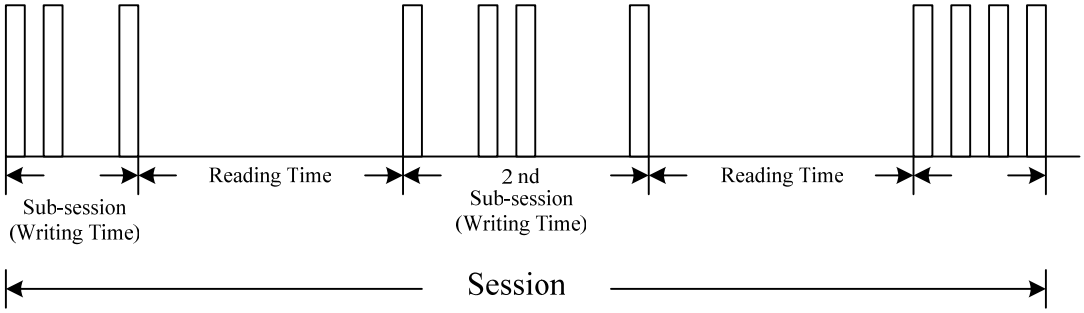

Figure 2 Email Traffic Pattern

Based on the Email traffic patterns, we list in the following the parameters governing the Email traffic characteristics with or without attachments in the Emails.

6.1 Email Protocol: POP3, MAPI

6.2 Number of Sub-sessions in one session

6.2.1 Number of Read sub-sessions: Lognormal distributed with mean $\mu_r = 30$ and standard deviation $\sigma_r = 17$

6.2.2 Number of Write sub-sessions: Lognormal distributed with mean $\mu_w = 14$ and standard deviation $\sigma_w = 12$

6.2.3 Read time per sub-session: Pareto distributed with $\alpha_r = 1.1,, k_r = 2, m_r = 65$, mean = 60 seconds, maximum = 63 seconds

6.2.4 Write time per sub-session: Pareto distributed with $\alpha_w = 1.1,, k_w = 2, m_w = 125$, mean = 120 seconds, maximum = 123 seconds

6.3 Email average header size: Deterministic , 1 K bytes

6.4 Email size without attachment:

6.4.2 Read (Receive) : Cauchy distributed, median $\mu = 22.7$ K bytes, 90%-tile = 80K bytes

6.4.3 Write (Send) : Cauchy distributed, median $\mu = 22.7$ K bytes, 90%-tile = 80K bytes

6.5 Email size with attachment:

6.5.2 Read (Receive) : Cauchy distributed, median $\mu = 227$ K bytes, 90%-tile = 800K bytes

6.5.3 Write (Send) : Cauchy distributed, mean $\mu = 227$ K bytes, 90%-tile = 800K bytes

Appendix: Some Important Probability Density Functions

A.1 Log-normal Probability Density Function

$$f_x = \frac{1}{\sqrt{2\pi}\sigma x}\exp\left[\frac{-(\ln x - \mu)^2}{2\sigma^2}\right], \quad x \geq 0$$

where μ is the mean and σ is the standard deviation.

A.2 Discrete Pareto Probability Density Function

$$f_x = \frac{\alpha k^\alpha}{x^{\alpha+1}}, k \leq x \leq m$$

$$f_x = \left(\frac{k}{m}\right)^\alpha, x = m$$

where α is the shape factor, and the random variable is interested in the range from k to m.

A.3 Exponential Probability Density Function

$$f_x = \lambda \ e^{-\lambda x}, \quad x \geq 0$$

where λ is the reciprocal of the mean value μ, and λ = 1/μ.

A.4 Cauchy Probability Density Function

$$f_x = \frac{b/\pi}{(x-a)^2 + b^2}, b > 0$$

where a is the median value and is the location parameter, b is the scale parameter. Mean and standard deviation of Cauchy distribution are not defined. With b= 1, the Cauchy distribution becomes:

$$f_x = \frac{1}{\pi((x-a)^2 + 1)}$$

A.5 Extreme Probability Density Function

$$f_x = \frac{1}{b} e^{-\frac{x-a}{b}} e^{-e^{\frac{x-a}{b}}}, b > 0$$

A.6. Uniform Probability Density Function

$$f_x = \frac{1}{b-a}, \quad a \le x \le b$$

A.7. Weibull Probability Density Function

$$f_x = \alpha\beta x^{\beta-1} e^{-\alpha x^{\beta}}, \quad x > 0$$

Where α is a scale factor and βis shape factor
