Current Suggestion

- The current 16m draft supports **frame** granularity for Sleep.
- Original motivation is not clear
 - 16e supports frame granularity, as this is the basic scheduling timeslot. It is not clear why this was not followed in 16m.

VoIP Scenario

– Assumptions

- 20ms interarrival time
- MS requires to receive a single DL subframe to receive the VoIP packet and HARQ feedback and 1 UL subframe to transmit HARQ feedback and send HARQ information.
- DL:UL = 4:4 (subframes).

Possible 16m Timeline – Frame Sleep

- Best case scenario (no retransmissions) → sleep 50% of the subframes

Possible 16m Timeline – Subframe Sleep

- Best case scenario → Sleep 29/32 = ~**90%** of the subframes
 - Power consumption reduction of ~**54%** (if we assume 5X active power over sleep power per subframe)

Conclusions

- Supporting Sleep with granularity of subframes is extremely important to further reduce MS's power consumption and thus increase its battery lifetime which is **a major requirement for a 16m MS**.
 - Also required to be competitive to LTE devices.
- HARQ timing and UL MAP relevance should also be considered to enable this tight sleep pattern.
- MS should not be forced to wake up on a superframe boundary to receive the SFH, since it can assume SFH will not be changed in most cases (MAP should include an indication of any change).
