Minimum Total Input Jitter Tolerance	0.51UIpp 10 ⁻¹²
Applied peak-peak sinusoidal jitter	5 x 10 ⁵ /f (100kHz < f <= 10MHz) 0.05UI (10MHz < f < 10 LB)
Eye Height	105mVpp

- Reference CRU and reference software CTLE used to calibrate the stressed receiver test signal at TP1a using a PRBS9 pattern.
- The crosstalk source is asynchronous to the main pattern generator. The crosstalk pattern is PRBS31. Target value: 900mVppd amplitude, 9.5ps 20-80% rise/fall). All lanes active.
- Module input test signal: DJ is added to a clean pattern by adding SJ, low pas filtering and limiting function. Variable gain is used to adjust amplitude. RJ is added such that the output of the limiting function approximates TJ = 0.28UIpp, RJ = 0.15UIpp, DCD = 0.035UIpp
- Frequency dependent attenuator is added such that the output of the limiter to TP1a is 10.25dB loss at 12.89GHz
- Eye height and eye width are measured using software CTLE with optimal peaking setting (maxim eye width * eye height
- RJ and variable gain is adjusted to result in the minimum eye height and eye width

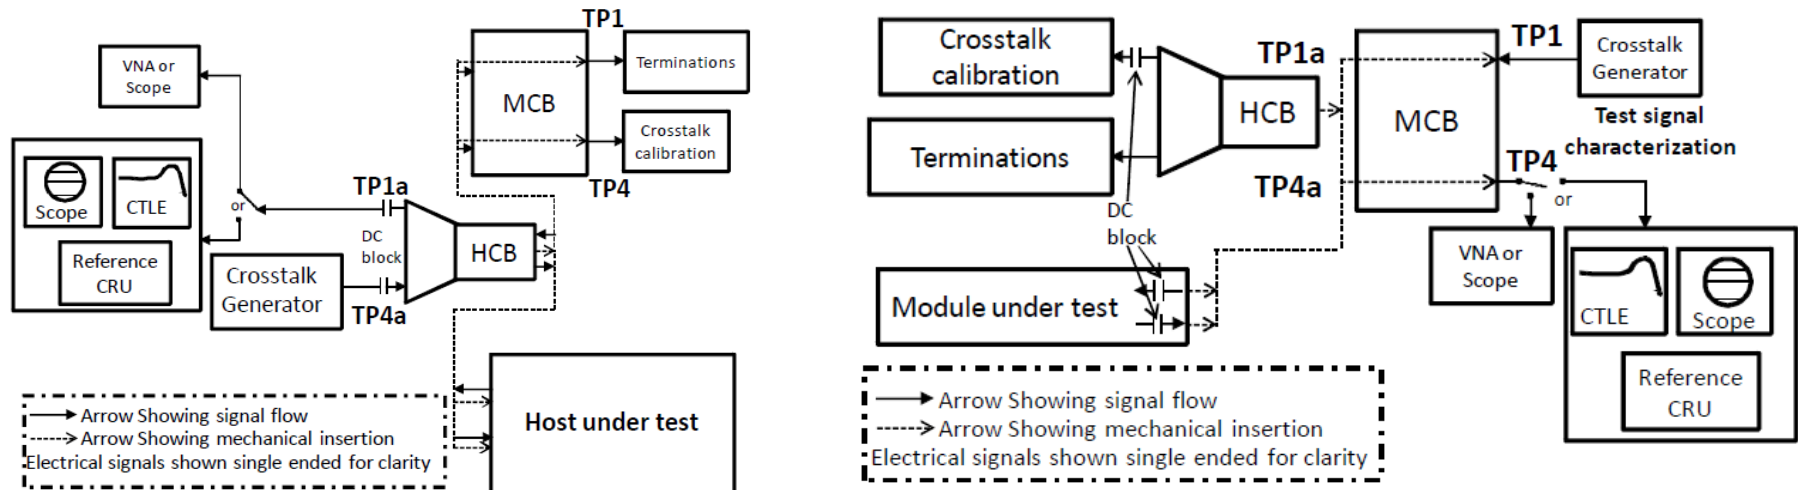

Host Stress Receiver Test

Host Stress Receiver Test	Eye Opening after reference CTLE
Minimum Total Input Jitter Tolerance	0.41UIpp 10^{-12}

Eye Height	245mVpp

- Reference CRU and reference software CTLE used to calibrate the stressed receiver test signal at TP4 using a PRBS9 pattern.

Host / Module Output Waveform Test

- The total jitter (TJ) of a signal is defined as the range (the difference between the lowest and highest values) of sampling times around the signal transitions for which the BER at these sampling times is greater than or equal to 10^{-12} . Total Jitter shall be less than [see spec]
- Use PRBS9 for channel under test
 - enables capturing waveform and reference CTLE
 - capture 4 million bits with 3 samples per bit to allow for post processing
- Dual-Dirac mathematical model to extrapolate to 10^{-12}
