Cl 00 SC 0 P175 L 27 # 3212

Remein, Duane Huawei Technologies

Comment Type T Comment Status X

EDITORS NOTE (to be removed prior to publication): the above variable definition of DS_FreqCh(n), taken from 45.2.1.109 should be moved to Cl 100 and referenced in the above para. The details in Cl 45 should be removed to avoid duplicate definitions and a cross reference to the location in Cl 100 provided. A complementary definition for the US OFDMA channel center frequency is also needed in Cl 100.

SuggestedRemedy

Move DS_FreqCh(n) definition to 100.2.7.1 Change definition in 101.4.2.10.1 to read: "See 100.2.7.1"

Change text of 45.2.1.109.1 from

"Register bits 1.1902.15:0 specify the center frequency, in steps of 50 kHz, of subcarrier 0 for the first OFDM channel. Subcarriers are numbered from 0 to 4095 with subcarrier 0 at the lowest frequency. This definition equates to a subcarrier 0 center frequency of from 54.0 to 3,276.75 MHz in 50 kHz steps. The minimum value for this register is 1080. See 101.4.2.12 for additional details."

To:

"Register 1.1902 specifies the center frequency for the first OFDM channel. This register is a reflection of the DS_FreqCh(1) defined in 100.2.7.1."

Similarly change 45.2.1.109.2 thru 45.2.1.109.5 to read:

"Register 1.190x specifies the center frequency for the second OFDM channel. This register is a reflection of the DS_FreqCh(x) defined in 100.2.7.1." Replacing x and second with the appropriate numbering.

Comment Type T Comment Status X

EDITORS NOTE (to be removed prior to publication): not all variables need to be included in CI 45. We need to determine how to index variables that need to be communicated over the PHY Link that are not included in CI 45. Current "rule" is:

If 1.1900 <= RegAdd <=1.1999 Then Index = RegAdd - 1.1900)*1000) (i.e., 0-99) as of Draft 1.3 38 indexes in this range were in use.

If 12.0000 <= RegAdd Then Index = (RegAdd - 12.0000)*1000 + 100 (i.e., 100 +)

SuggestedRemedy

For variables defined in CL 45 MMD 1 use register address minus 1900 per current rule.

This will result in indices of 0 - 38 for currently defined registers.

For variables not defined in Cl 45 use index of 500-999

For variables defined in Cl 45 MMD 12 use register address + 1000. Thus registers 12.0000 to 12.10241 will use indices 1000 to 11241.

Update Tables 100-1, 101-1, 102-3 and 102-13.

Remove editors note.

Remein, Duane Huawei Technologies

Comment Type T Comment Status X

No such variable as NxtCNU ID, Shouldn't ref Cl 45 as normative.

SuggestedRemedy

Change 3 instances of NxtCNU ID to AllwdCNU ID.

Strike references to Cl 45 in this para: "(see 45.2.1.117)", "(see 45.2.1.120)" and "(see 45.2.1.121)"

Add "variables" to very end of para so it reads: "... write the CNU PHYTimingOffset and PHYPowerOffset variables."

Add the following definitions to 102.4.1.7.2

AllwdCNU_I

TYPE: 15-bit integer

This variable is used to indicate to the 10GPASS-XR PHY a valid CNU_ID value. The value may be assigned to a new CNU when the associated CNU_ID assigned flag is set to zero, when the flag is set to one it is an indication that this value has already been assigned to a CNU and it should not be use for another CNU.

DS_OFDM_ID

TYPE: 3-bit integer

This variable is a pointer to one of the five possible OFDM channels in the downstream EPoC network. Thus when DS_OFDM_ID is set to a value of one variables DS_ModTypeSC(n) reflect the OFDM descriptor for OFDM channel one. When DS_OFDM_ID is set to a value of two variables DS_ModTypeSC(n) reflect the OFDM descriptor for OFDM channel two, etc.

In 45.2.1.117.2 pg 45 ln 13 change:

"See 102.4.1.6 for additional details on the use of these bits."

to:

"These bits are a reflection of the AllwdCNU I variable defined in 102.4.1.7.2."

In 45.2.7a.1 pg 49 ln 51 add the following:

"These bits are a reflection of the DS_OFDM_ID variable defined in 101.4.2.3.5.

Cl 101 SC 101.3.2.5.2 P131 L15 # 3264

Remein, Duane Huawei Technologies

Comment Type TR Comment Status X

This para has little to do with LDPC encode process and more rightly belongs in 101.3.2.2 (which points to Cl 49).

"The 64B/66B encoder produces a stream of 66-bit blocks as shown in Figure 101–6 (see 49.2.4.3 for more details); each 66-bit block is composed of 2 bits of sync header and 64 bits of data. These 66-bit blocks are converted to 65-bit blocks by removing the redundant first bit (i.e., sync header bit <0>) in each 66-bit block received from the 64B/66B encoder and are then delivered to the FEC encode and Data Detector input process. The FEC encoder accumulates BQ (see Table 101–2) of these 65-bit blocks to form the payload portion of the FEC codeword." In addition the referenced material in Cl 49 includes a scrambler within the 64/66B encoder and is not appropriate for EPoC as we scramble in the PMA layer.

Similar text with similar issues lives in 101.3.2.5.6 pg 135 ln 9

See related comments against wording in 101.3.2.5.2 & 101.3.2.5.6

SuggestedRemedy

Remove the para's from 101.3.2.5.2 & 101.3.2.5.6

Change 101.3.3.2 to read:

"The EPoC PHY utilizes a 64B/66B decoder based on that described in 49.2.11 with several important differences. The EPoC 64B/66B encoder does not include a scrambler function and the output is a 65B block with a single synch header bit as illustrated in Figure 101-11. The state diagram found in Figure 49-16 is followed. The 66-bit blocks produced by the Clause 49 64B/66B encoder are shortened to 65-bits by removing the redundant first bit (i.e., sync header bit <0>). These 65-bit blocks are then delivered to the PMA as described in 101.4.1.2."

Proposed Response Status O

C/ 101 SC 101.3.2.5.2 P131 L15 # 3263

Remein, Duane Huawei Technologies

Comment Type T Comment Status X

The para beginning "The 64B/66B encoder produces a stream of 66-bit blocks as shown in Figure 101–6 ..." does not describe the LDPC encoding process.

SuggestedRemedy

Remove the para and reword this section to read:

"The process of padding FEC codewords and appending FEC parity octets in the 10GPASS-XR CLT PCS transmit path is illustrated in Figure 101–6. First the FEC encoder accumulates BQ 65-bit blocks (see Table 101–2) to form the payload portion of the FEC codeword. Next, the FEC encoder calculates the CRC40 (see 101.3.3) over the aggregated BQ 65-bit blocks, placing the resulting 40 bits of CRC40 code immediately after the BQ 65-bit blocks, forming the payload portion of the FEC codeword. Finally, the FEC encoder appends BP (see Table 101–2) padding bits (with the binary value of "0") to the payload of the FEC codeword as shown in Figure 101–6. The resulting FP bits are then passed to the LDPC-encoder . The LDPC-encoder generates FR bits of parity. After encoding, the encoder deletes the BP bits of padding and constructs the output codeword with a length of (FP - BP) + FR bits; i.e., (14400 - 60) + 1800 = 16140 bits. For transmit processing in the downstream direction, the codeword size is a constant and is represented by constant FEC DS CodeWordSize (see 101.3.2.5.2).

Proposed Response Status O

Two definitions for FEC CW size which are nearly identical. These need to be more clearly differentiated.

FEC_CODEWORD_SIZE

TYPE: integer

This constant represents the size of FEC codeword in octets (FEC_PAYLOAD_SIZE +

FEC_PARITY_SIZE).

Value: 1987

FEC CODEWORD SIZE FRAC

TYPE: real number

This constant represents the exact size of the FEC codeword in octets.

Value: 1760+2944/13 This is confusing.

SuggestedRemedy

NOT FINAL

Change definitions as show below

FEC_CODEWORD_SIZE

TYPE: integer

This constant represents the approximate size of the downstream FEC codeword in whole

octets (FEC PAYLOAD SIZE + FEC PARITY SIZE).

Value: 1987

FEC CODEWORD SIZE FRAC

TYPE: real number

This constant represents the exact size of the FEC codeword in whole and fractional octets.

Value: 1760+2944/13 (1760 +(1840*64/65/8)

Comment Type T Comment Status X

The MER variables here are not reflected in any clause variable table (that I can find). MER values will be calculated as part of the CNU and CLT receive Pilot Processing, Equalization, and FFT functions in the PMA. Note to us that we may need to add some extra words into the FFT subclause to require MER calculation.

SuggestedRemedy

Suggest adding MER variables into Table 101-1, page 112-114. Editor's discretion on naming and placement.

Comment Type T Comment Status X

Need to resolve TBD's or not modify Clause 67. Nominal reach is first defined in ammendments to Table 56-1, page 63 as "2.9 km" with table footnote of "Maximal differential distance between CNUs. Reach may vary depending on the CCDN."

Note that Table 67.1 has not been updated with other EPON PHY standards that increase split ratio beyond 1:16, e.g. 1:32, 1:64. Since EPoC does not specify the maximum number of CNUs, the number of PHYs = CLT PHY + N * CNU PHYs is not readily quantifiable into this table format.

SuggestedRemedy

Consider 1 of 2 choices:

Choice 1: do not modify Clause 67 and remove from our draft.

Choice 2: try to fill in the TBD's with something that makes some sense:

Page 67, Lines 27 and 28, replace nominal reach TBDs with "2.9" and add a table footnote same as "i" from Table 56-1. Note now that this is duplicative of the changes to Table 56-1.

Page 67, Lines 27 and 28, replace number of PHYs TBD with "variable" and a new table footnote "Based on cable operator's CCDN configuration, the number of PHYs will be the

CLT PHY plus each CNU PHY." or similar.
