

1x400G vs 4x100G FEC Implications

IEEE P802.3bs 400 Gb/s Ethernet Task Force

July 2015 Hawaii

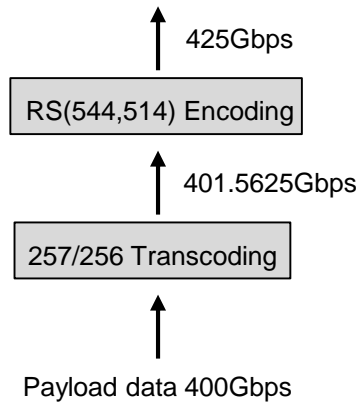

Bill Wilkie – Xilinx

Introduction

- This presentation takes a look at the differences in implementation of a 1x400G and a 4x100G FEC architecture
- The implementation types/styles are just some valid options, there are many ways to implement each architecture
- The sizing data presented is a combination of real design data and the results from micro architecture analysis and extrapolation

Data Rates

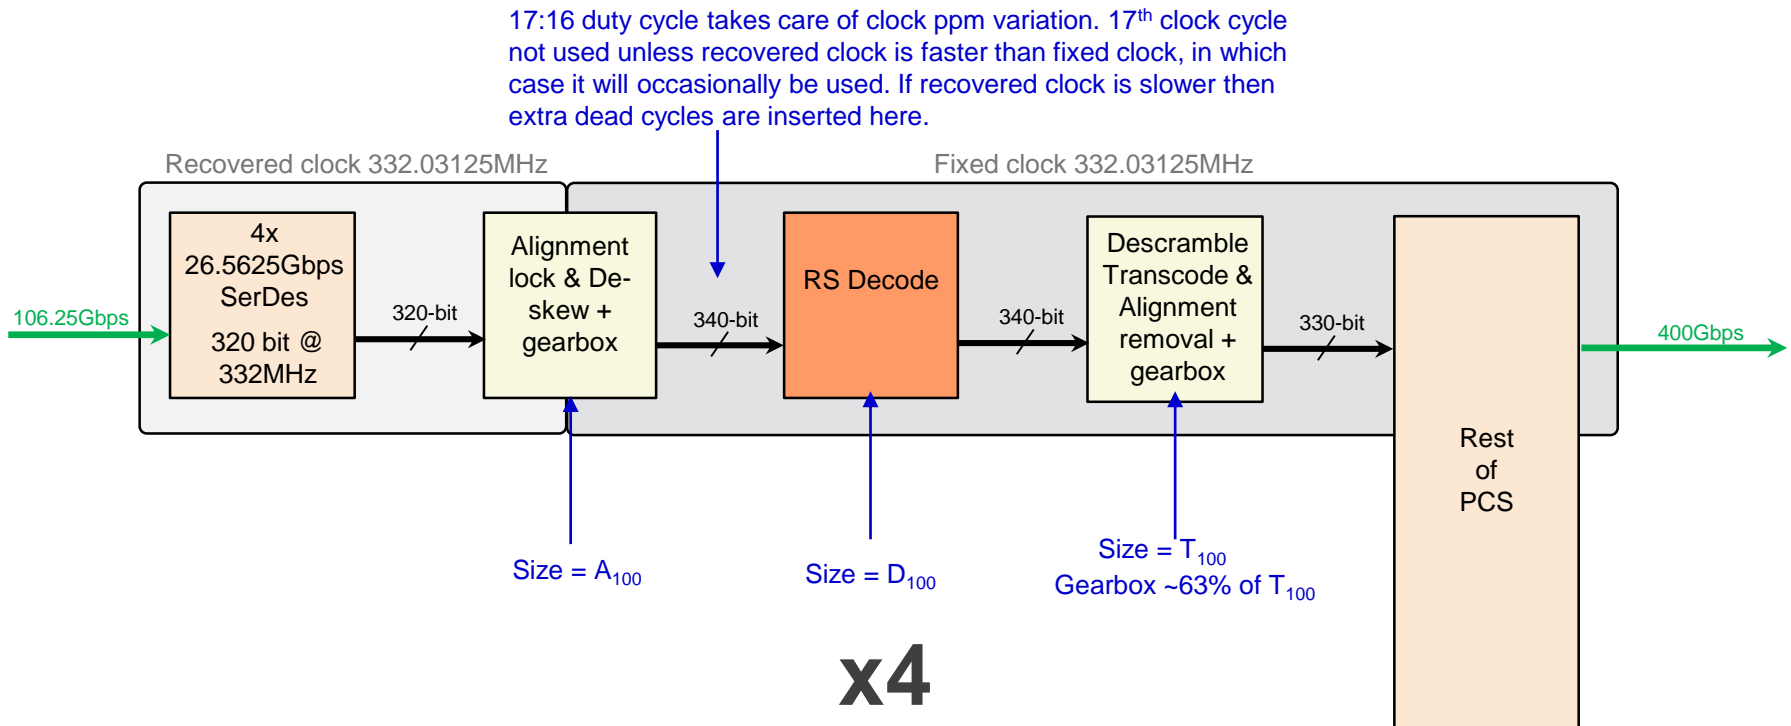

- These bus widths, clock frequencies and data rates are investigated in this presentation

Input	Input Data Rate	Input Width	Nominal Input Clock Frequency	Cycles per RS Codeword
KP4 400Gbps FPGA	425Gbps	1280	332.03125MHz	4.25
FPGA RS Decoder	451.5625Gbps	1360	332.03125MHz	4
KP4 400Gbps ASIC	425Gbps	640	664.0625MHz	8.5
ASIC RS Decoder	451.5625Gbps	680	664.0625MHz	8

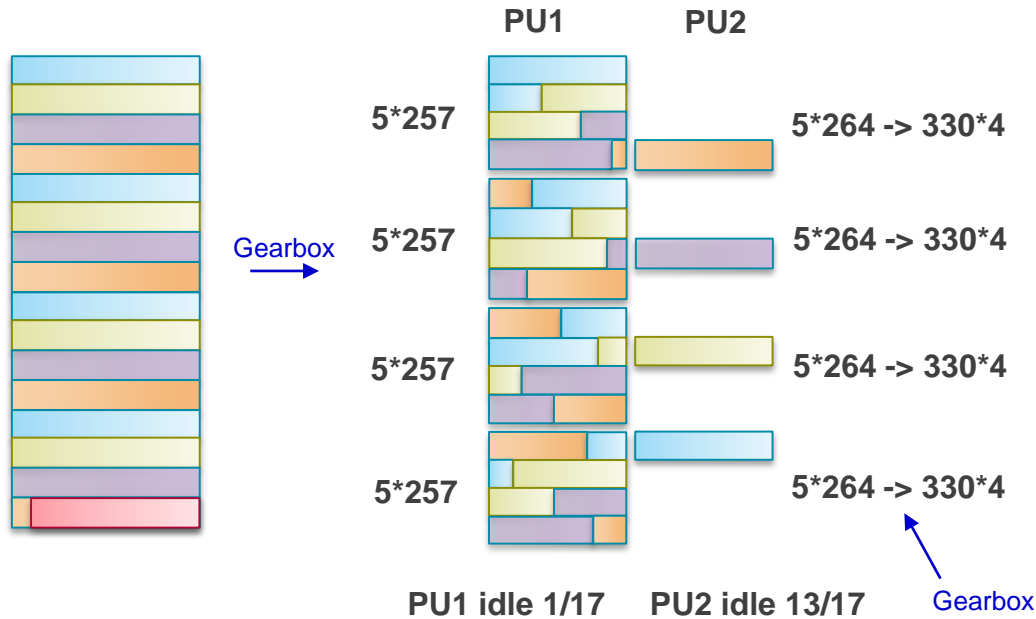

4x 100G KP4 Datapath: 340-bit Decoder

- Current FPGA appropriate bus widths and clock frequencies
- Uses free running local clock for most of the circuitry
 - Running off a local clock with periodic gaps eases design issues with unstable clocks
- Gearboxing from 320b to 340b is essentially free since this logic is used for alignment, re-ordering etc.

100G Transcode Gearboxing: 340-bit Decoder

➤ Gearbox complexity is high for this option

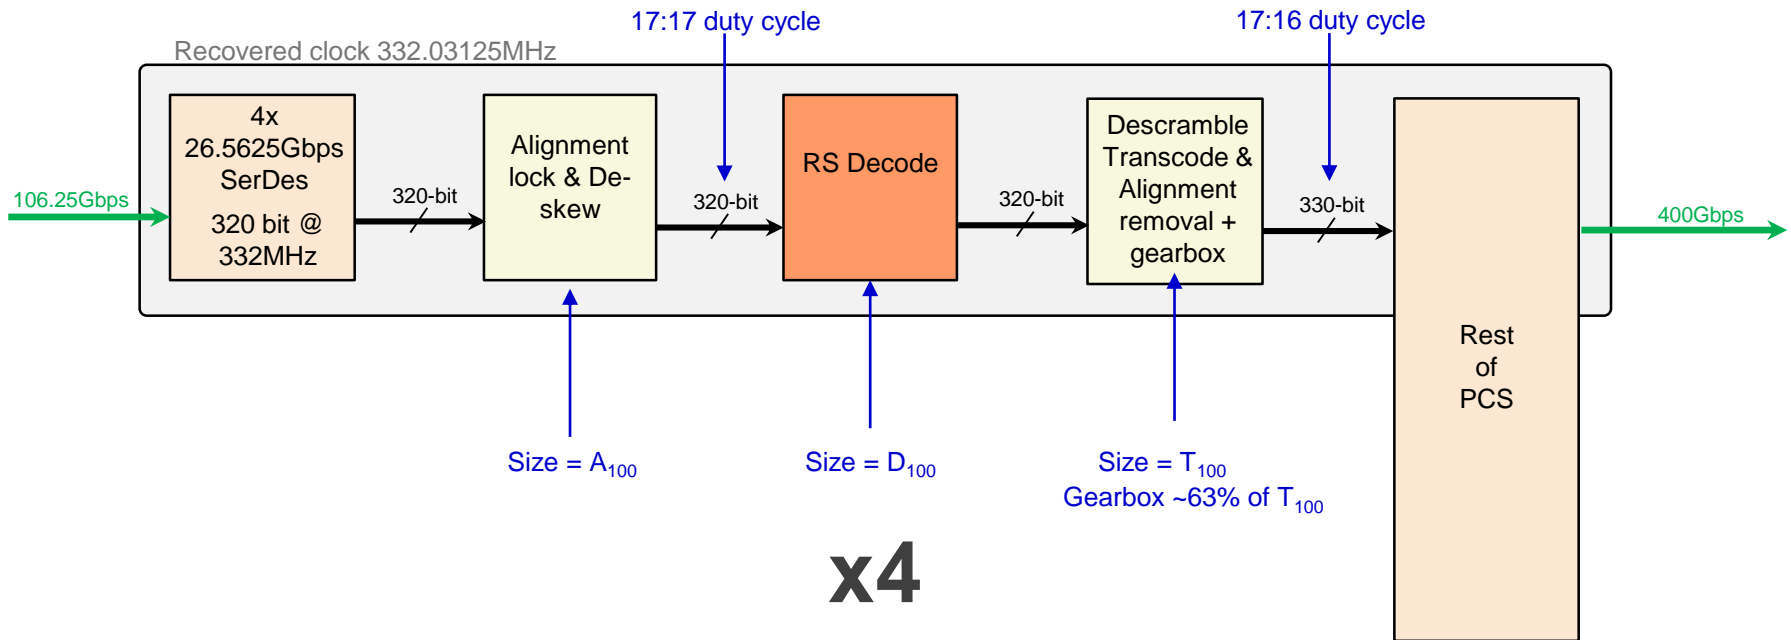

Buffer input mux is 16:1
 PU1 Gearbox mux is 16:1
 PU2 Gearbox mux is 4:1
 Output gearbox needed to convert from 5*264 to 4*330

 = parity

Complex gearbox + 2 Processing Units (PU)

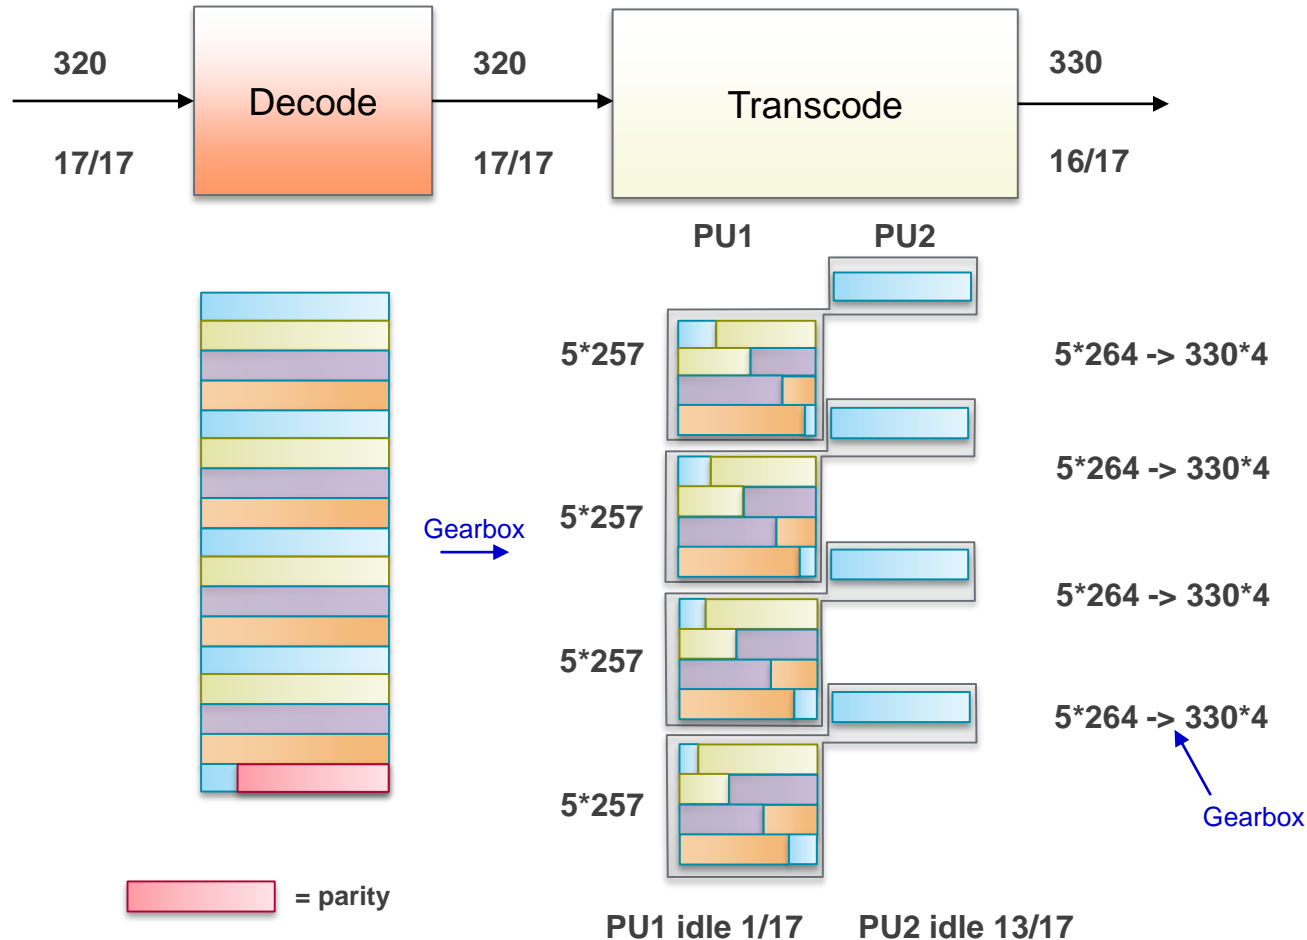

4x 100G KP4 332MHz Datapath: 320-bit Decoder

- Current FPGA appropriate bus widths and clock frequencies
- Uses recovered clock for all of the circuitry
- No gearbox required on Alignment lock and De-skew

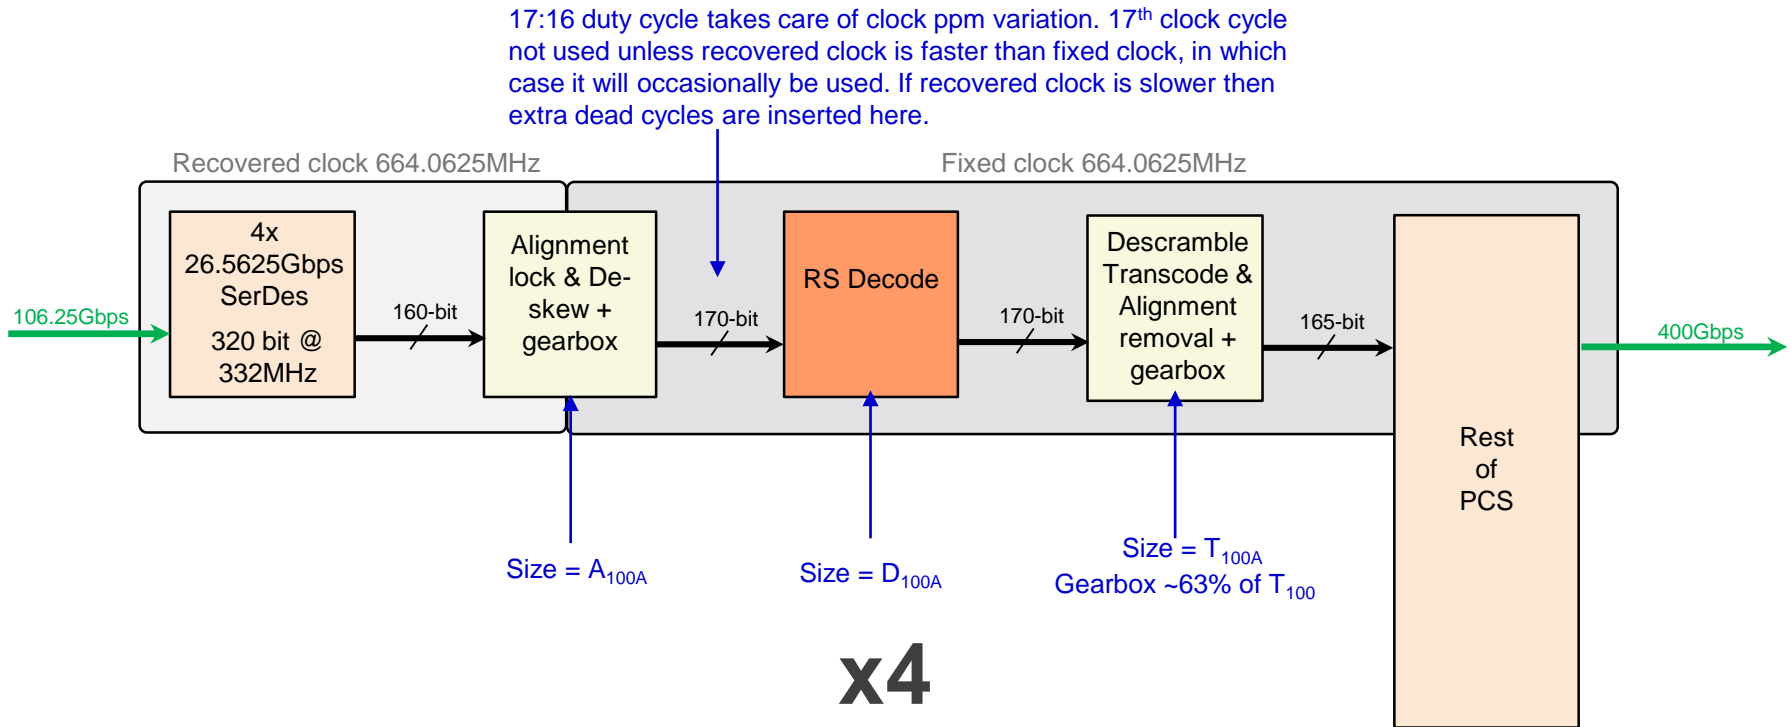

100G Transcode Gearboxing: 320-bit Decoder

- Gearbox complexity is high for this option, similar to the 340b decoder

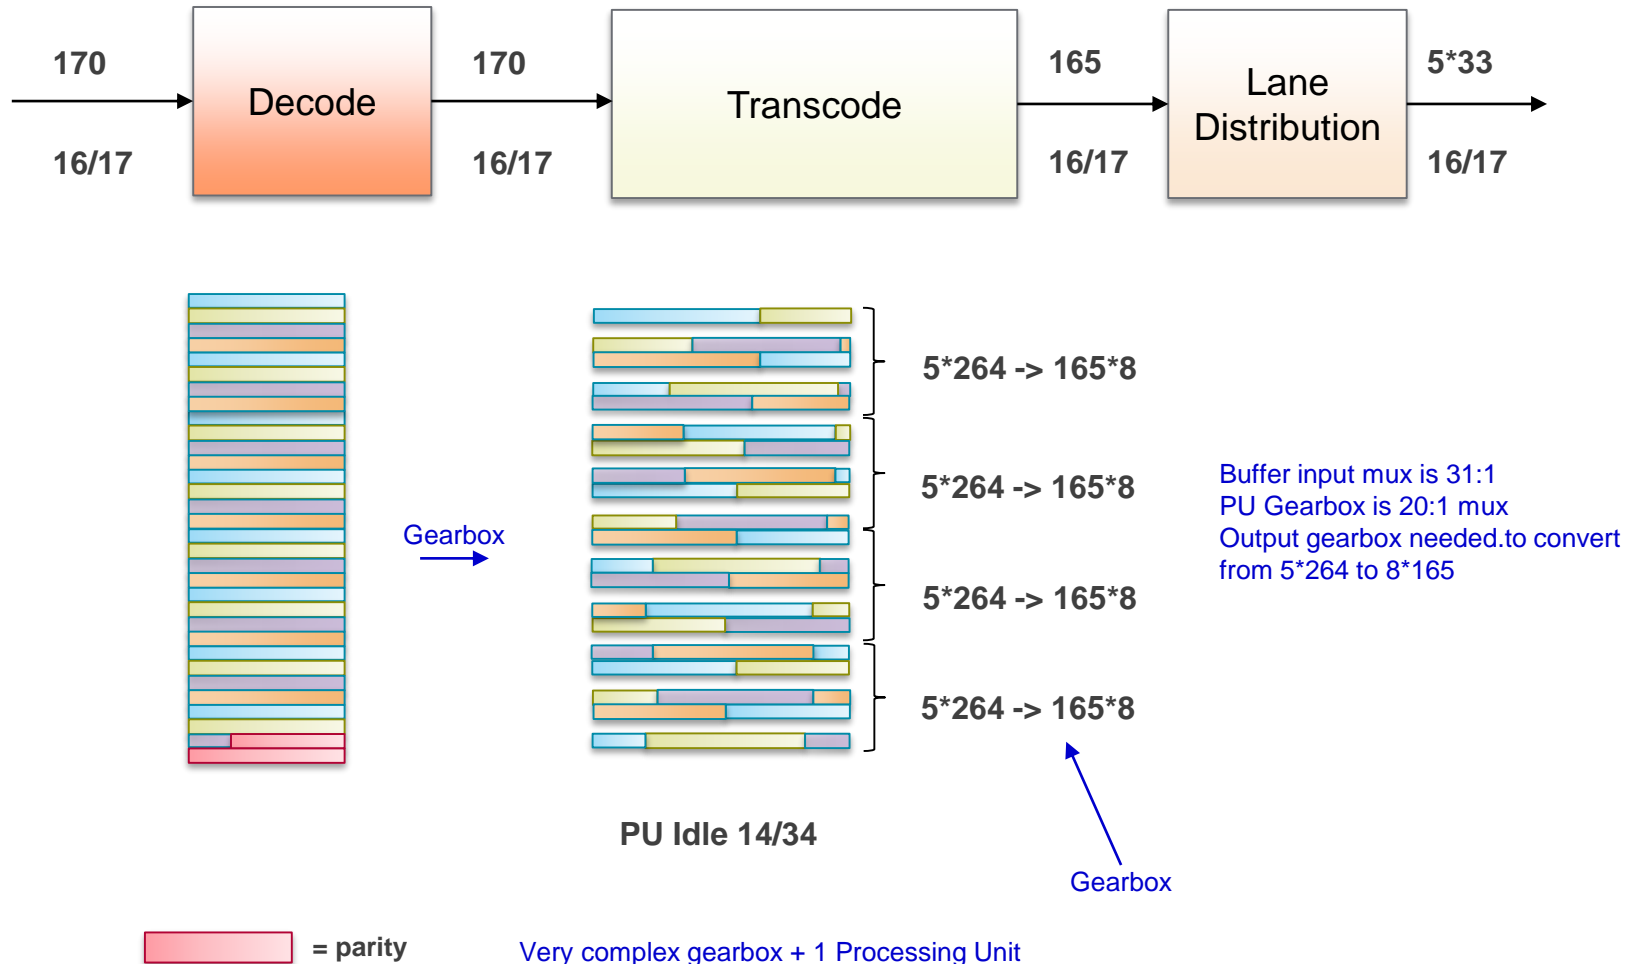

4x 100G KP4 Datapath: 170-bit Decoder

- Current ASIC and future FPGA appropriate bus widths and clock frequencies
- Uses free running local clock for most of the circuitry
 - Running off a local clock with periodic gaps eases design issues with unstable clocks
- Gearboxing from 160b to 170b is essentially free since this logic is used for alignment, re-ordering etc.

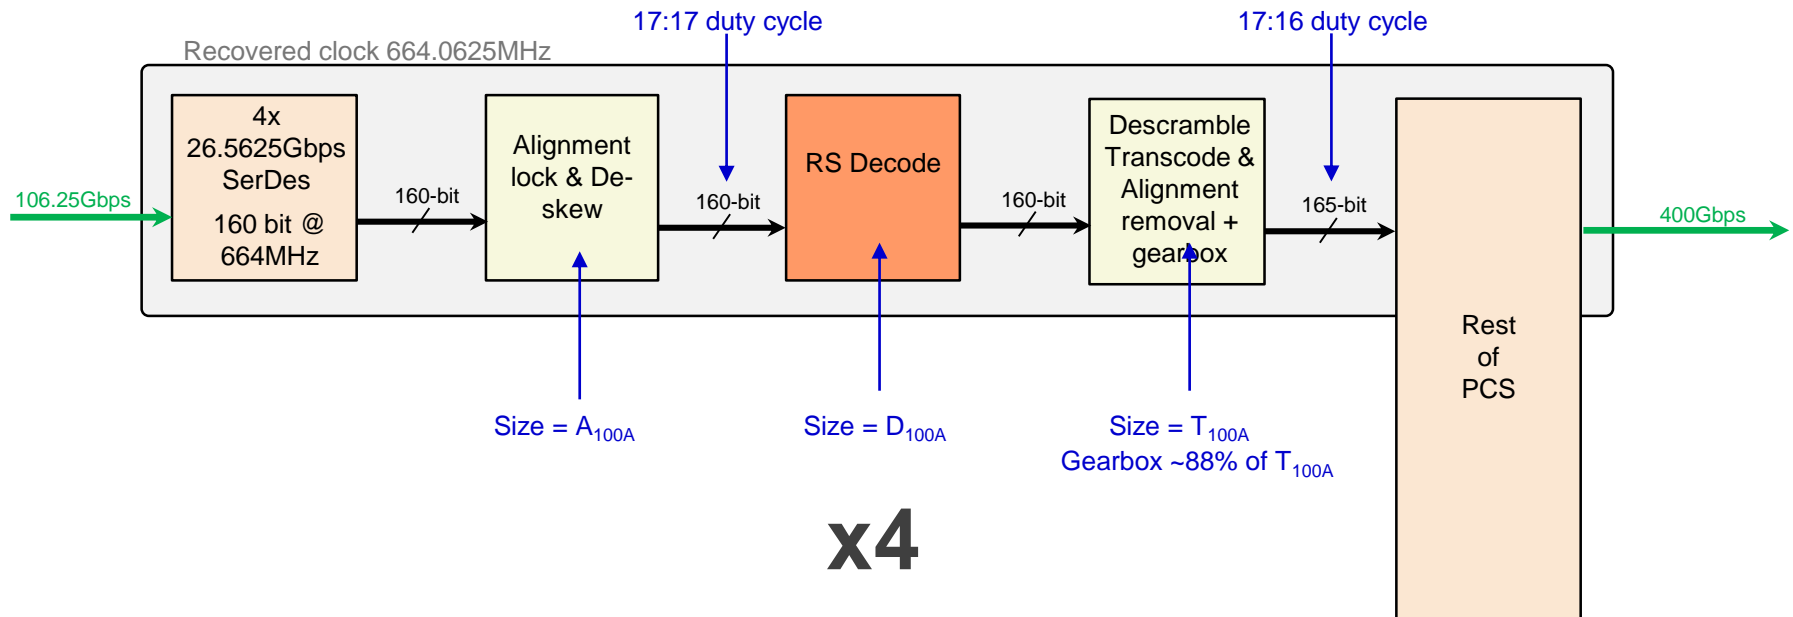

100G Transcode Gearboxing: 170-bit Decoder

➤ Gearbox complexity is high for this option

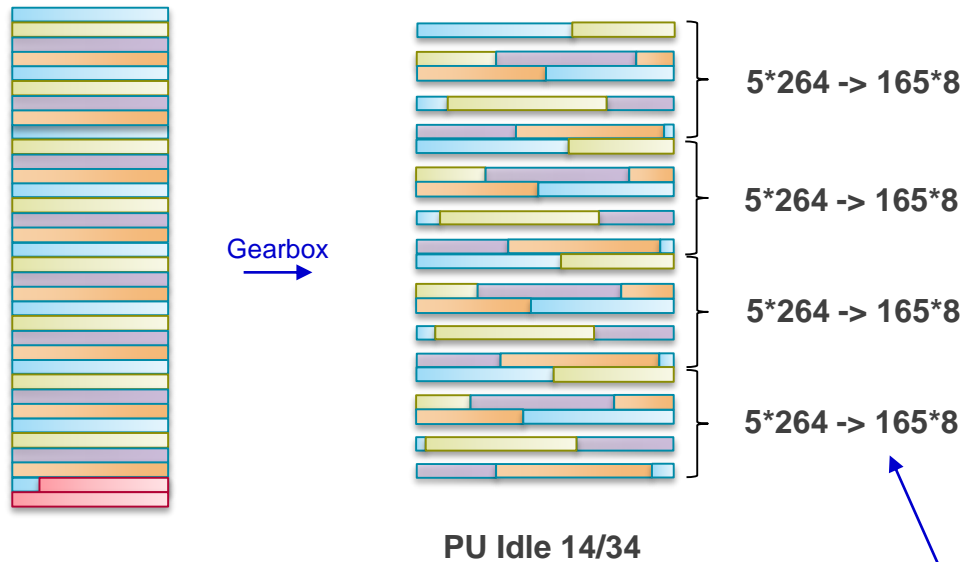

4x 100G KP4 664MHz Datapath: 160-bit Decoder

- Current ASIC and future FPGA appropriate bus widths and clock frequencies
- Uses recovered clock for all of the circuitry
 - Drawback of dealing with a potentially unstable clock
- No gearbox required on Alignment lock and De-skew

100G Transcode Gearboxing: 160-bit Decoder

➤ Gearbox complexity is high for this option

Buffer input mux is 33:1
 PU Gearbox is 20:1 mux
 Output gearbox needed to convert
 from 5*264 to 8*165

 = parity

Very complex gearbox + 1 Processing Unit

Gearbox

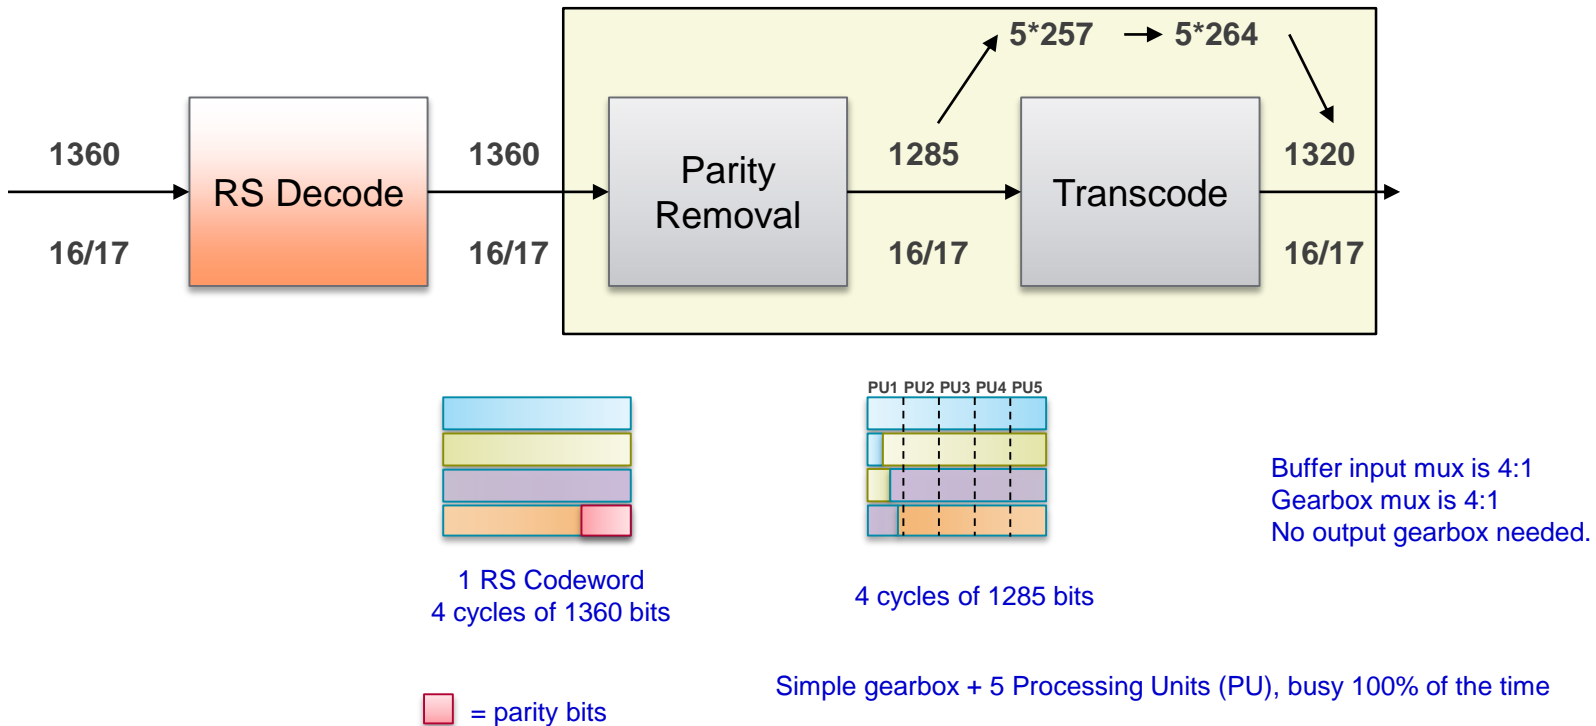

1x400G KP4 332MHz Datapath

- Current FPGA appropriate bus widths and clock frequencies
- Uses free running local clock for most of the circuitry
 - Running off a local clock with periodic gaps eases design issues with unstable clocks
- Gearboxing from 1280b to 1360b is essentially free since this logic is used for alignment, re-ordering etc.

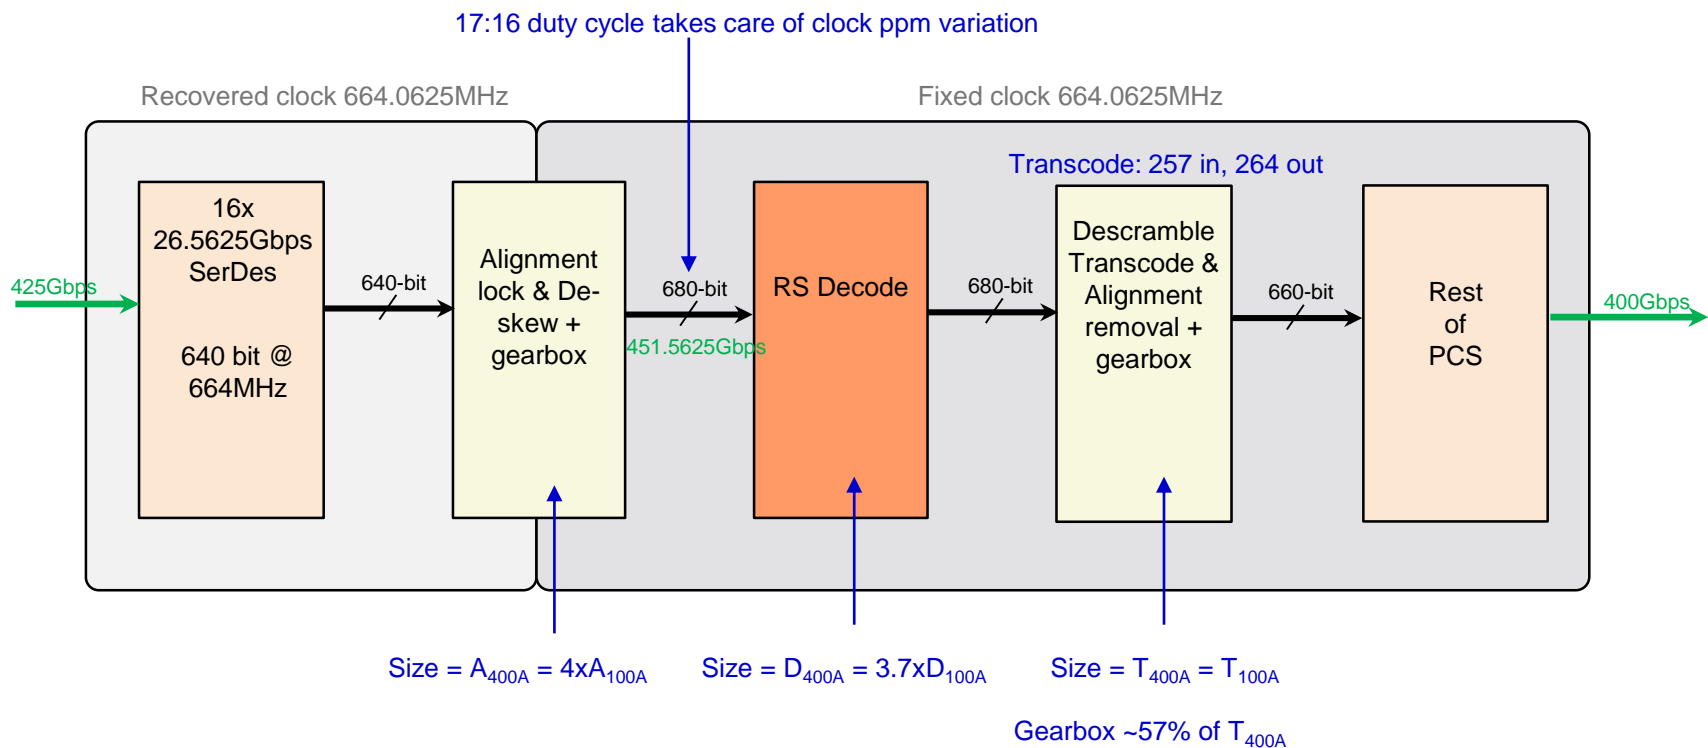

1x400G Transcode Gearboxing: 1360-bit Decoder

➤ Low complexity gearboxing for this option

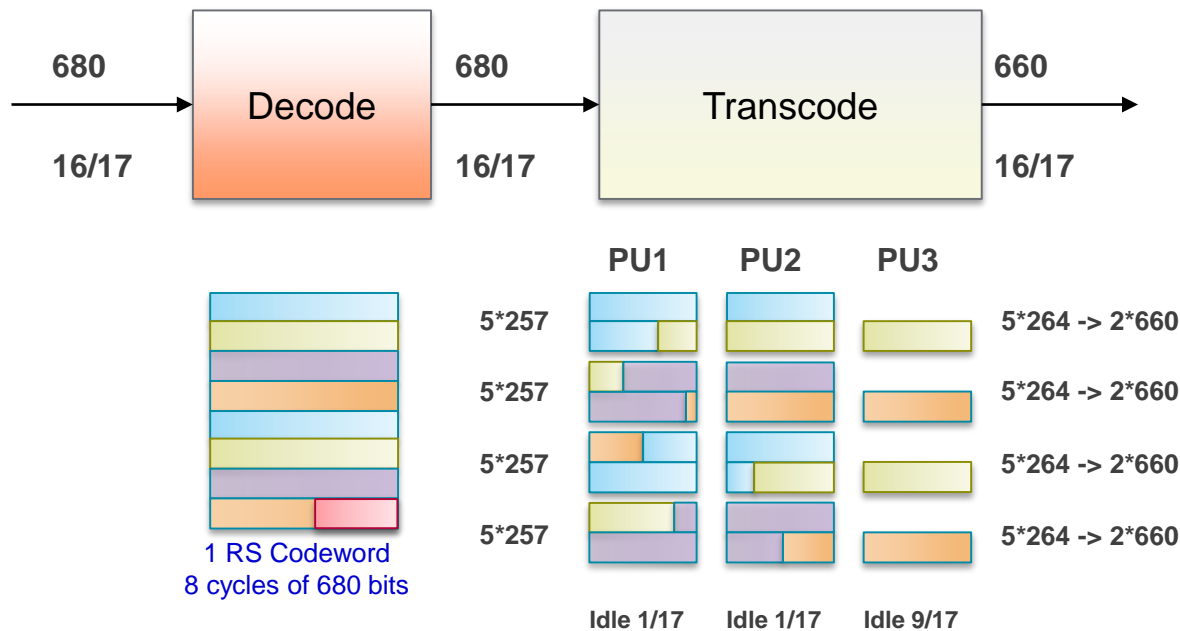

1x400G KP4 664MHz Datapath

- Current ASIC and future FPGA appropriate bus widths and clock frequencies
- Uses free running local clock for most of the circuitry
 - Running off a local clock with periodic gaps eases design issues with unstable clocks
- Gearboxing from 640b to 680b is essentially free since this logic is used for alignment, re-ordering etc.

400G Transcode Gearboxing: 680-bit Decoder

➤ Medium complexity gearboxing for this option

Gearbox + 3 Processing Units

Buffer input mux is 8:1
 PU1 & PU2 gearbox mux's are 8:1
 PU3 gearbox mux is 4:1
 Output gearbox needed to convert from 5*264 to 2*660

Size Comparison: 332MHz Clock

➤ 4x100G (KP4)

- 100G RS Decoder, size = D_{100}
- 100G Alignment, lock and de-skew & gearboxes, size = $A_{100} \approx 0.131D_{100}$
- 100G Transcode, alignment removal & gearboxes, size = $T_{100} \approx 0.094D_{100}$
- 4x100G overall size = $4 * (D_{100} + A_{100} + T_{100}) \approx 4.9D_{100}$

➤ 1x400G (KP4)

- 400G RS Decoder, size = $D_{400} \approx 4D_{100}$
- 400G Alignment, lock and de-skew & gearboxes, size = $A_{400} \approx 4A_{100}$
- 400G Transcode, alignment removal & gearboxes, size = $T_{400} \approx 1.35T_{100}$
- 400G overall size = $D_{400} + A_{400} + T_{400} \approx 4.7D_{100}$

Size Comparison: 664MHz Clock

➤ 4x100G (KP4)

- 100G RS Decoder, size = D_{100A}
- 100G Alignment, lock and de-skew & gearboxes, size = $A_{100A} \approx 0.187D_{100A}$
- 100G Transcode, alignment removal & gearboxes, size = $T_{100A} \approx 0.272D_{100A}$
- 4x100G overall size = $4 * (D_{100A} + A_{100A} + T_{100A}) \approx 5.84D_{100A}$

➤ 1x400G (KP4)

- 400G RS Decoder, size = $D_{400A} \approx 3.68D_{100A}$
- 400G Alignment, lock and de-skew & gearboxes, size = $A_{400A} \approx 4A_{100A}$
- 400G Transcode, alignment removal & gearboxes, size = $T_{400A} \approx 0.94T_{100A}$
- 400G overall size = $D_{400A} + A_{400A} + T_{400A} \approx 4.68D_{100A}$

Conclusion

- Both 4x100G (KP4) and 1x400G (KP4) architectures are implementable in both current ASIC and FPGA technology
- Gearboxing on either side of the decoder is not a concern, the logic is already there to do this function as part of the other required functions
- A 1x400G FEC architecture has a small size advantage
