

# IEEE 802.1aq

## migration control for Mac-in-Mac Hash/TTL

### B-VID

# Background

- 802.1aq defines a new VLAN behavior.
  - Traffic on an SPB BVLAN within a domain takes shortest path.
- Other behaviors also exist, e.g., STP, PBB-TE.
- 802.1Q has mechanisms to ensure B-VID behavior is consistent within a domain (Configuration Digest).
- To change the algorithm for an SPB B-VID 802.1aq has mechanisms to advertise and verify consistency.

# Background

- The ECT algorithm for a SPB B-VID is defined with a tuple:

{ B-VID,ECT-ALGORITHM}

- The ECT-ALGORITHM identifier is further broken down into a world wide unique OUI and local 'index'.
- 802.1aq currently defines 17 identifier values, all with the 802.1 OUI. These use indexes 0..17.
- Index 0 is for the CIST while indexes 1..17 are for algorithms with different ECT tie breakers.

# Tuples are exchange/verified

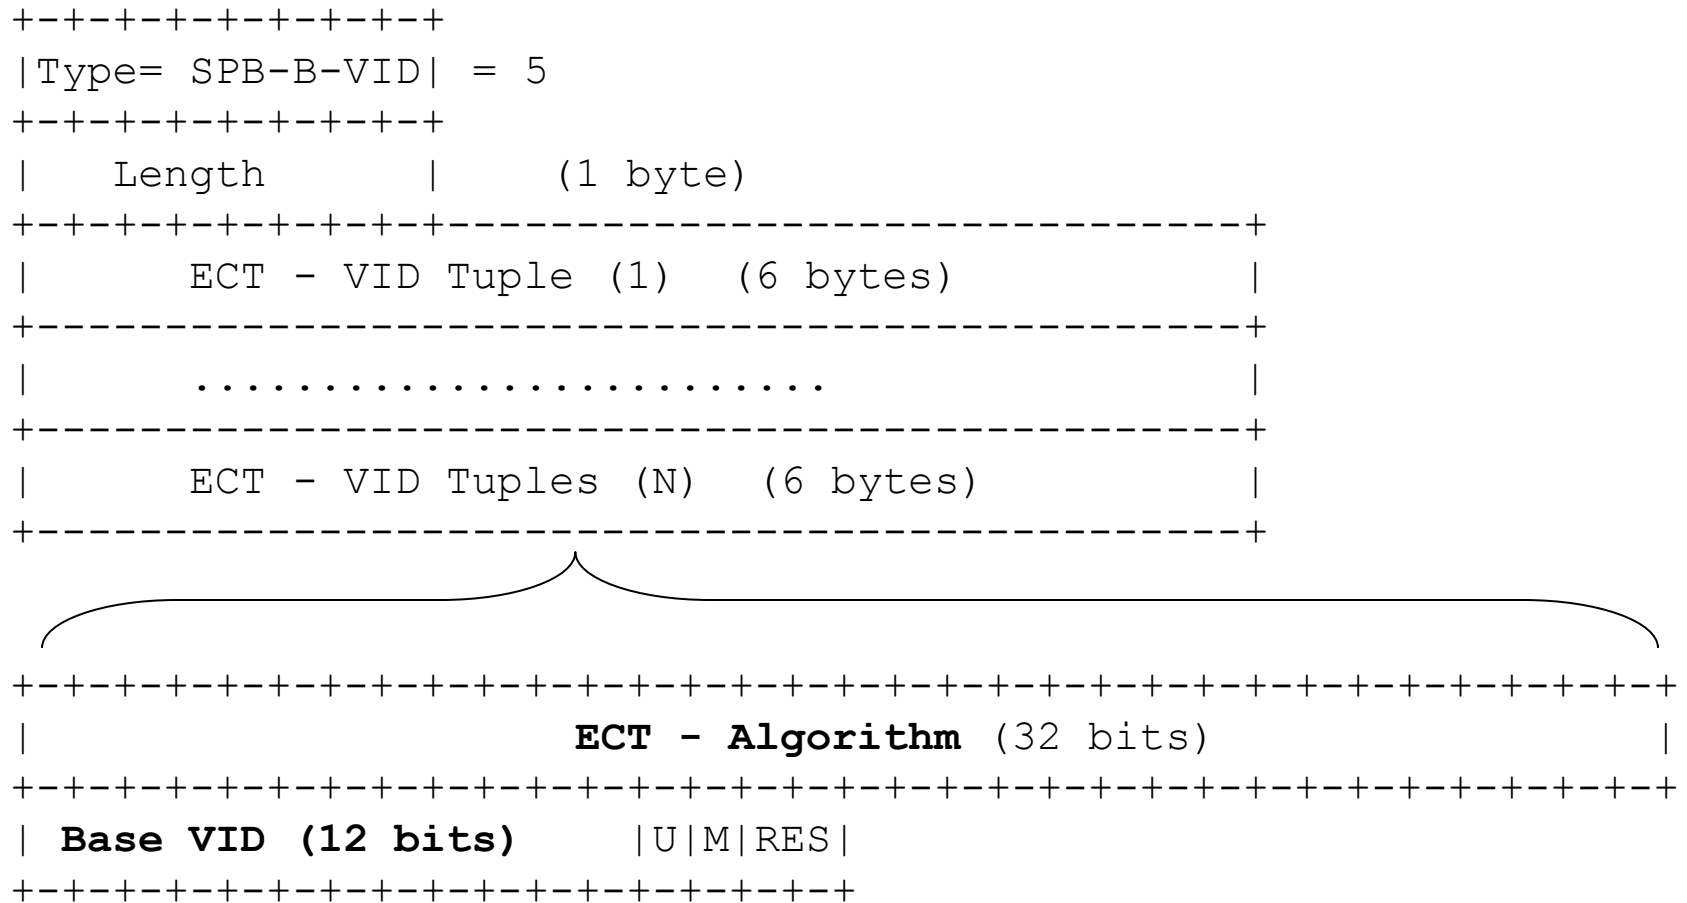

Inconsistency is only permitted if a tuple (B-VID) is **not in use**.

We can therefore introduce a new {B-VID,ECT-ALGORITHM} and temporary inconsistency is allowed until we start using it.

We can therefore remove all services from a B-VID and then start to delete the associated {B-VID,ECT-ALGORITHM} and inconsistency is allowed while I delete it.

Service migration to/from a new {B-VID,ECT-ALGORITHM} only requires edge re-provisioning, can be done over days/weeks.

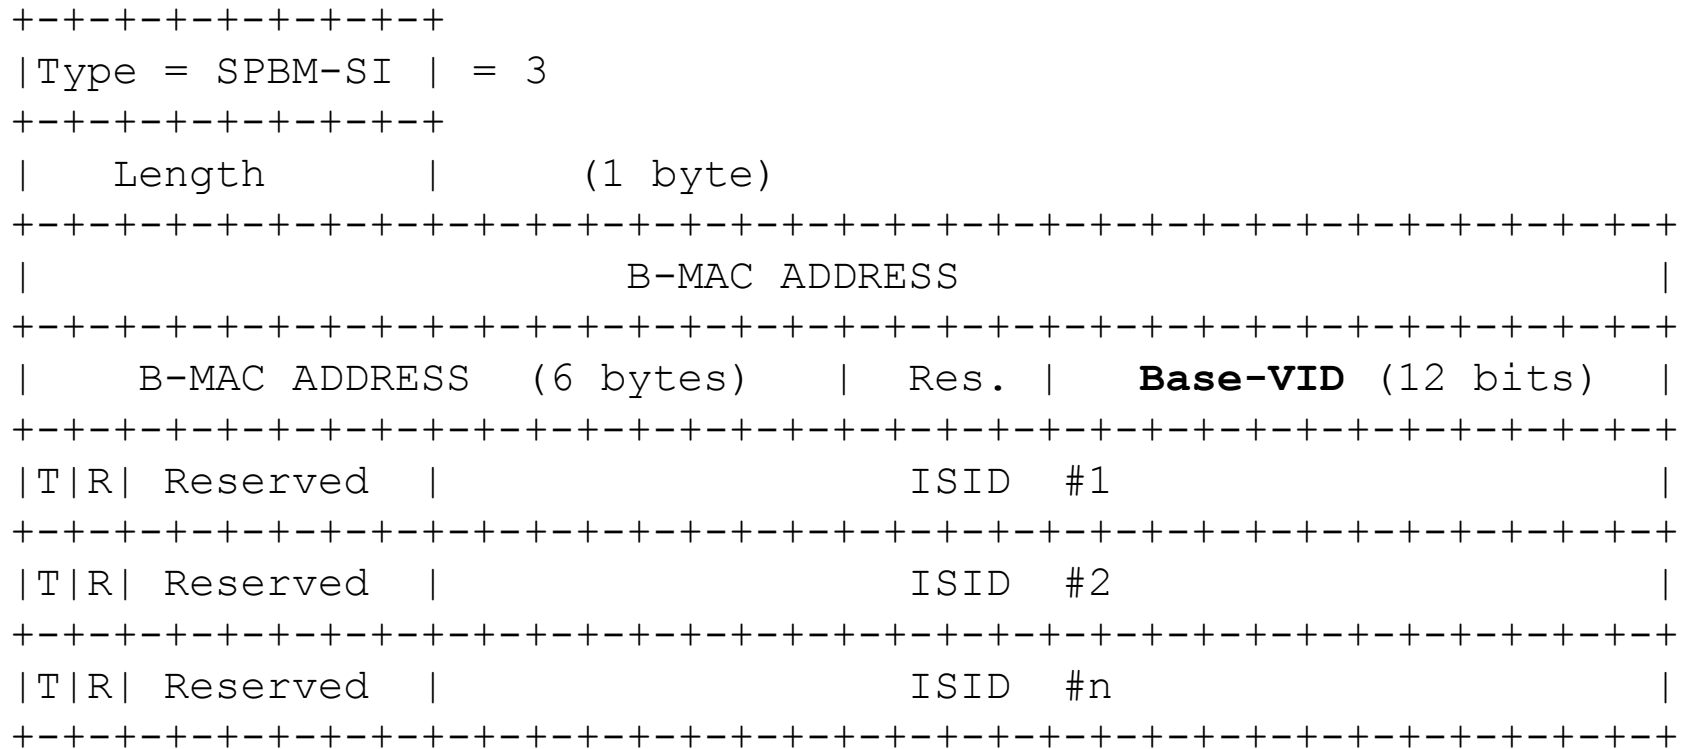

# Algorithm to B-VID association in Hello

# Algorithm to B-VID association in LSP.

# TLV – SPB-Service Instance

A service is assigned to an ALGORITHM indirectly through association with a Base-VID. The Base-VID is part of an {B-VID, ECT-ALGORITHM} tuple.

# Suggested approach for ECMP

- Assuming an 802.1aq network running some number of ECT-ALGORITHMS.
- A new {B-VID,ECT-ALGORITHM} tuple is assigned and advertised normally.
- The new {B-VID,ECT-ALGORITHM} would use hash-based forwarding/TTL decrement for UNICAST traffic only.
- Migration of services to/from this B-VID would be identical to any other B-VID running an AQ ECT algorithm.
