

Lightweight Network Network Interface

Using Link Aggregation

Rev. 2

ENNI: Heavy or light?

There are at least two distinct methods we can pursue for defining an Ether NNI:

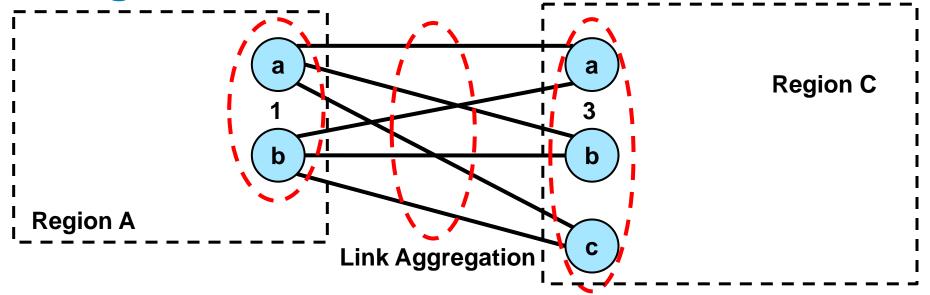

Heavy:

A Buffer Network is built along the lines suggested in new-nfinn-buffer-networks-0310-v01.pdf with an explicit data encapsulation.

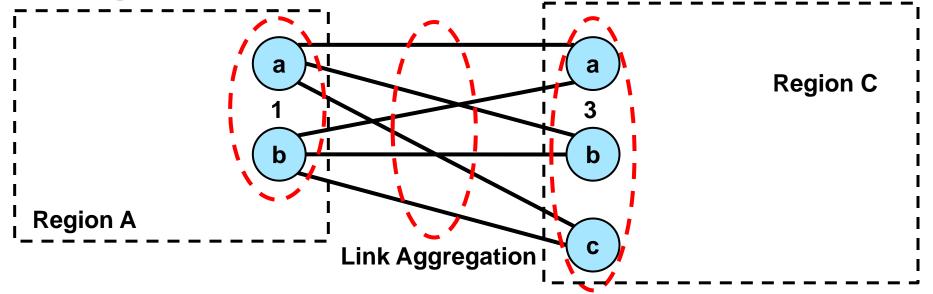

Light:

Buffer Network is built using "virtual nodes," i.e. the multiple physical Nodes of each Portal cooperate to give the appearance of a Portal consisting of a single Node. This present document is new-nfinn-light-nni-0710-v02.pdf.

 Each method has its advantages and drawbacks, and all of the drawbacks can be addressed. This is a classic engineering decision.

- The Terminal Nodes in each Region appear, to the other Region, to be a single Terminal Node (bridge, switch, or whatever).
- All of the inter-Region Links are combined into a single Aggregated Link using LACP.
- Links among Nodes in the same Region are invisible and irrelevant to the ENNI.

- The means by which the Virtual Terminal Nodes are implemented does not need to be standardized; this author sees no requirement for 3a, 3b, and 3c to come from three different vendors.
- The choice of physical link is always up to the transmitting Virtual Terminal Node, and the receiving Virtual Terminal Node must live with the choice.

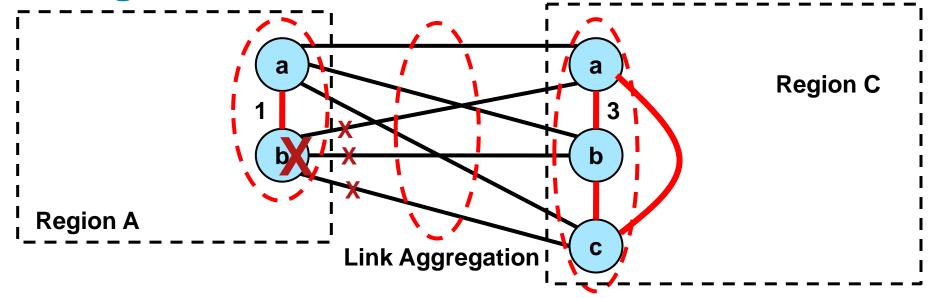

- Physical level CFM can be used to improved failure detection time for the physical links; we do not have to depend on LACP's (slow) timeouts.
- Obviously, the two Regions have to agree on a data encapsulation, but a 1:1 service encapsulation translation can be performed at either (or both) ends, and no encapsulation-dependent CFM is required.

Light ENNI – issues

- Clearly, service-based physical link selection is preferred to other methods, e.g., hashing the IP 5-tuple.
- For efficiency of routing, a means (perhaps LACP extensions) should be provided for one Region to express a preference (not a demand) for which link should be used for which service.
- For optimum maintainability, it we should provide a means for the two Virtual Terminal Nodes to agree to use the same physical link for both directions for a given service (or bundle of services).
- This means does not necessarily have to be dynamic over the NNI; passing a digest of an agreed Link assignment might be sufficient.

Light ENNI – Node failure

- The physical components of a Virtual Terminal Node appear to be a single Node to the other Region.
- Whether they appear a single Node to their own regions is not a concern of this standard.
- If one component of a Virtual Terminal Node fails (say 1b) then its attached Links fail, but the remaining Nodes (1a in this case) continue to function; recovery is quick.

Service Assignment across NNI

Bundles of Services

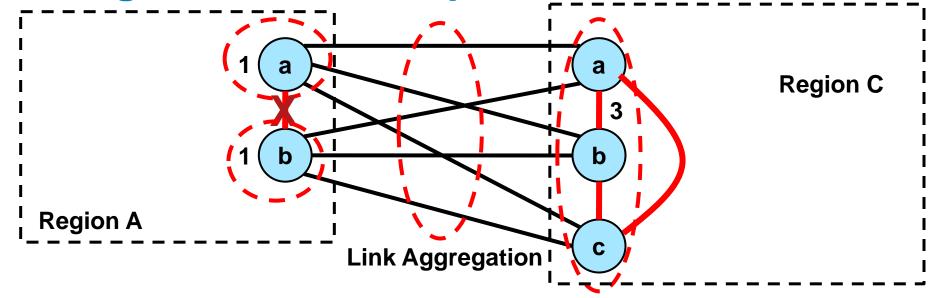

- We cannot express link preferences for thousands of services in an LACP or CCM PDU; some kind of "bundling" is necessary across the ENNI, if preferences are signaled explicitly.
- But, if we configure the list of Service-to-physical Link assignments for every possible combination of available physical Links, then no extra run-time protocol (other than configuration checksum comparison) is required across the NNI.
- This seems preferable to any dynamic algorithm, because it is amenable to human negotiation and judgment, and not subject to "priority assignment wars."

Exchanging Link Assignment across NNI

- Just like MSTP, a Link Assignment Database has a "Link Assignment Identifier (LAID)" consisting of a name, a revision number, and a hash function, so that it is very unlikely to accidentally think you are in sync with your neighbor when you are not.
- Just like MSTP in BPDUs, the LAID is carried in every LACPDU.
- Better yet, carry an old and a new LAID, so that a graceful transition can be made when the configuration changes. Details to be worked out.

Split brain detection = Graceful name change

Light ENNI – Intra-pair Link failure

- If the Link between two components of a Virtual Terminal Node (e.g. 1a-1b) fails, both components can takeover the Node's identity, but act independently (the "split brain" scenario), with disastrous results.
- For this reason, "inter-VTN links" are made extrareliable, and in some existing proprietary implementations, are assumed to be failure-proof.

Light ENNI – Split brain detection

- We cannot (in the author's opinion) design a network standard around "failure proof links".
- Since we are assuming that LACP is being used to establish Aggregated Links between Virtual Terminal Nodes, we could enhance LACP so that the devices connected to a Virtual Terminal Node can assist the VTN in detecting a "split brain" scenario.
- But, split brain detection is necessarily a hippity-hippity-hop operation, involving multiple Nodes; there is no equivalent to the Maintenance Associations described for the Heavy ENNI. Split brain detection will be slower than MA failure detection.

Light ENNI – Split brain recovery

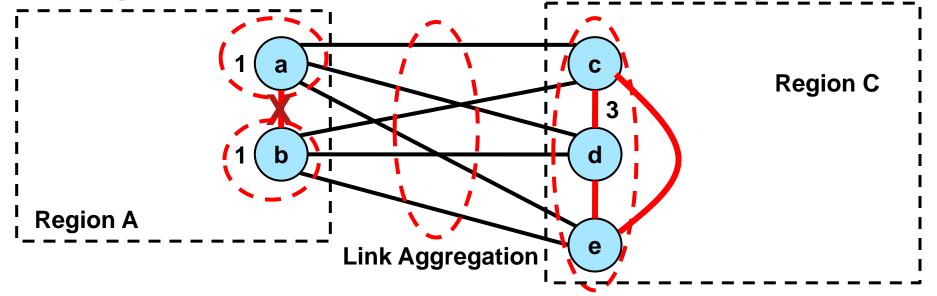

Recovery from the split brain is up to the implementation:

Some implementations may have no issues with a split brain.

Some implementations may shut down an isolated secondary component of the virtual node.

Some implementations may change identities to become two separate devices (equivalent to shut down for the ENNI, since the "light" scheme requires a single virtual node).

 Signaling the recovery choice can be handled with current LACP, e.g., by removing Links to one of the physical Nodes from the aggregation.

- Let us suppose that, if the a-b Link fails, then device a continues to use the virtual device name as its Actor_System field, but device b changes its name to a new Actor_System field based on its own physical ID.
- If either a or b really failed, then c, d, and e will continue to use the link to the remaining system.
- If only Link a-b failed, then c, d, and e will each pick a.

- All that is needed is:
 - A means for c, d, and e to not disrupt the aggregation while b changes its name.
 - Assurance that c, d, and e will all pick the same Node (a or b) when Link a-b fails.
- The first can be accommodated by adding an "Old Actor_System_Priority" and "Old Actor_System" TLV to LACP. This allows a system to change its name without disrupting an ongoing aggregation.
- The second can be done by requiring c, d, and e to select the link with the lower numerical Actor_System_Priority and Actor_System to continue with the NNI.

Now, if Node a fails:

- Nodes c, d, and e, all lose their Links to Node a, but continue to use the Links to Node b.
- Node **b** changes its Actor_System name, but that causes no further disruption.

If Node **b** fails:

 Nodes c, d, and e, all lose their Links to Node b, but continue to use the Links to Node a.

If Link a-b fails:

- Node **b** changes its Actor_System name, and that causes
 Nodes **c**, **d**, and **e** to disaggregate from Node **b**.
- Node **b** has no one to talk to.

If Node a recovers:

- Nodes **c**, **d**, and **e**, all switch over to using Node **a**.
- Node b changes its Actor_System name to match Node a's name, so all Links are back in use.

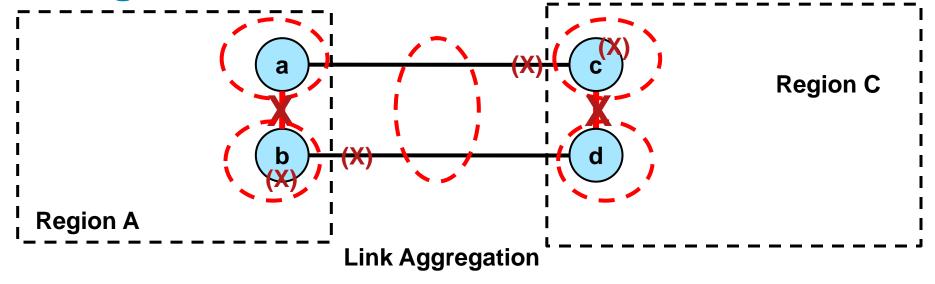

If Node **b** recovers:

Nodes c, d, and e, regain their Links to Node b.

If Link a-b recovers:

- Node **b** changes its Actor_System name to match that of Node
 a.
- Nodes c, d, and e, return their Links to Node b to the aggregation.

Light ENNI – bad choice of master brains

- Suppose the recovery method for "split brain" is that the secondary device shuts down.
- If a and d, above, are "master" nodes, then if both inter-VTN links fail (as shown), the ENNI would fail.
- Indicating in LACP which is the master node would enable the administrators to make a and c the master nodes, so that the a—c link would remain operational.

NNI criteria list

- All of the criteria are met, though some of them simply become requirements on the multi-chassis Bridge implementation. Some requirements need comment.
- Protect a single service (VLAN) or a group of services (VLAN).
 - We add bundle preferences to LACPDU.
- Support interconnection between different network types (e.g. CN-PBN, PBN-PBN, PBN-PBBN, PBBN-PBBN, etc.)
 - This method works even for MPLS!
- Provide sub-50 ms fault recovery
 - Probably. We must look at the Split Brain situation further.

- The effects of protection events in one network must not affect other networks.
 - This requirement is placed on the multi-chassis bridge implementation, in one sense. In another sense, the multichassis bridge is required to accept a service on any Link.
- Design the interconnected zone in a way that will ensure determinism and predictability.
 - LACP works this way, now.
- It must be possible to ensure the use of the same link in both directions for every service.
 - This why we are introducing the Bundle Preferences TLV.

- The NNI protects services, not parts of services.
 - We must make this type of Aggregation mandatory.
 - Presence of Bundling TLV announces this.
- If one service provider cloud becomes split into multiple disjoint clouds, it cannot depend on the interconnect cloud or any adjacent service provider cloud to provide connectivity among its parts.
 - This is inherent in LACP a frame transmitted over the aggregated Link cannot be returned, any more than it can be returned on a single physical Link.
- We cannot assume an ultra-reliable link.
 - This is why we are extending LACP for split-brain detection.

- Support asymmetrical links -- not all the same speed or cost
 - Symmetry is an arbitrary imposition, at present.
 - There is need to specify how to dynamically split the services over unequal speed Links if the decision is mandated by configuration.
- Do we support an encapsulation scheme in the interconnect cloud, or is the ENNI independent of the encapsulation?
 - Independent!

- Do we assume that the bandwidth (or other Traffic Engineering parameter) of the interconnect cloud is adequate for all of the services, or do we do something special if it is insufficient?
 - If the Link usage is pre-configured, this is taken care of (some Bundles or Services may be dropped in certain situations).
- Do we need protocol for conveying service creating/deletion or traffic engineering requirements between Service Providers?
 - Good question! To Be Determined. But if so, it should be part of a separate PAR in this author's opinion.
