

TSN Explicit Route Installation: IS-IS or SRP

Rodney Cummings
National Instruments

TSN Assumptions (My Opinion)

- We don't speak "service provider"
 - Local network ("customer" or "user")
 - Loosely connected to Internet
 - IETF & 802.1 ISIS-SPB technologies are useful, but
 - Translation is required; this presentation is an attempt
- Transition of existing time-sensitive Ethernet networks to 802.1 TSN will not increase cost or complexity
 - Example: Embed bridge chip in end-station
 - No additional CPU for bridge protocols (control plane)
 - Control-plane protocols use ~5-10% of existing CPU
 - Relative usage of each 802.1 bridge protocol is important

Path Computation Element (PCE)

- Some TSN features may be computationally complex
 - Explicit routes for redundancy (disjoint)
 - 802.1Qbv schedules
 - Network-wide latency analysis for credit-based shaper
- PCE concept = focus complexity where it is practical
 - Avoid complexity in all devices
 - PCE can be one device, or a few
 - PCE can be bridge, or end-station
 - For TSN, PCE can be talker or listener

PCE Workflow for Explicit Routes

| Step | | |
|-------------------------------------------------------------|--|--|
| 1. Implicit routes | | |
| 2. PCE learns topology and metrics | | |
| 3. PCE performs calculation | | |
| 4. PCE installs explicit routes into IS (bridges / routers) | | |
| 5. Bandwidth / stream reservation over explicit routes | | |

PCE Workflow for ER: IETF

| Step | Typical IETF | |
|-------------------------------------------------------------|---------------------------------|--|
| 1. Implicit routes | Mixed (IGP like IS-IS, or OSPF) | |
| 2. PCE learns topology and metrics | Mixed (ISIS-TE, OSPF-TE, ...) | |
| 3. PCE performs calculation | (not standardized by IETF) | |
| 4. PCE installs explicit routes into IS (bridges / routers) | RSVP-TE | |
| 5. Bandwidth / stream reservation over explicit routes | DiffServ | |

PCE Workflow for ER: IETF and TSN

| Step | Typical IETF | Proposal for TSN |
|-------------------------------------------------------------|---------------------------------|-----------------------------------|
| 1. Implicit routes | Mixed (IGP like IS-IS, or OSPF) | Mixed (STP like ISIS-SPB or MSTP) |
| 2. PCE learns topology and metrics | Mixed (ISIS-TE, OSPF-TE, ...) | 802.1Qca (IS-IS) |
| 3. PCE performs calculation | (not standardized by IETF) | (not standardized by 802.1) |
| 4. PCE installs explicit routes into IS (bridges / routers) | RSVP-TE | Extensions to SRP (SRP-TE) |
| 5. Bandwidth / stream reservation over explicit routes | DiffServ | SRP |

Step 1: Implicit Routes

- TSN cannot mandate IS-IS **computation** everywhere
 - Contradicts the goals of the PCE concept
 - Adversely impacts adoption of TSN
- ISIS-SPB mixes well with MSTP today
 - Need to continue this mixed support for TSN
 - Also support mix with S2IS...

S2IS Is a Great Start

- S2IS meets many TSN requirements

<http://www.ieee802.org/1/files/public/docs2013/new-iwk-nfinn-simple-isis-node-0713-v02.pdf>

- ✓ Avoids computation
- ✓ Bridge stores its own information only
- ✓ Solves step 2: PCE learns topology & metrics
- ✗ Limited to daisy-chain
 - Many TSN bridged end-stations require more than two external ports
 - Key point: TSN physical topologies are typically “engineered” (no loops)

- Reality check: Not all bridges run implicit routing
 - Many “Unmanaged” don’t run a Spanning Tree Protocol (STP)
 - Many of these bridges are used in time-sensitive applications today
 - S2IS could help transition these products into 802.1 visibility

Three Proposals to Improve S2IS

1. Allow > 2 “trunk” (external) ports
 - Same egress behavior as proposed for 2-port only
 - Assume end-user knows to avoid physical loops
2. Ring (802.1CB) requires one Full IS-IS bridge
 - Use full implicit routing to resolve intentional loops
3. 802.1Q PICS: Add S2IS as a routing option
 - 802.1Q-2011 requires one of: TMPR, RSTP, MSTP, SPB
 - We presumably need a new PAR for S2IS
 - Need a new name if no longer 2-port

Step 2: Learn Topology & Metrics

- TSN can mandate IS-IS distribution
 - Required as step 2 of PCE concept
 - Optional if PCE concept is not used (e.g. AVB Gen 1)
 - Optional for portions of network where PCE is not used
 - Can run MSTP in those portions
 - Specify in a TSN (Gen 2) standard
 - Similar to 802.1BA

Steps 3 and 5

- Step 3: PCE Performs calculation
 - Inherently PCE-specific... no standard needed
- Step 5: Reservation
 - For TSN, consensus is SRP, as described in “Model 2” of
 - <http://www.ieee802.org/1/files/public/docs2012/new-avb-anfredette-srp-spb-v02.pdf>
 - Non-TSN applications use IS-IS as alternative to SRP
 - Concept: PCE performs computation, bridge allocates bandwidth
 - 802.1Qca D0.4 has text for this; We may need 802.1Qcc text
 - For a new reader of 802.1, the direction should be clear
 - TSN (Gen 2) standard: TSN shall use SRP, not IS-IS

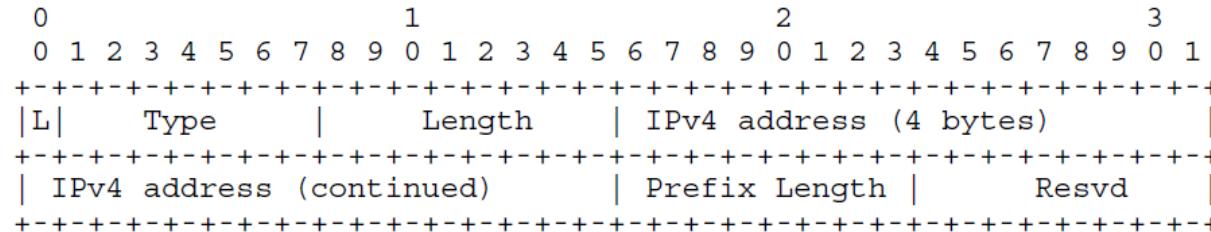

Remaining Slides: Step 4, PCE Installs Explicit Routes into IS

IETF Installation of Explicit Routes

- No proof-point for using link-state routing (IS-IS)
 - Assumed reason: Store explicit route only along its route
 - Not in every bridge and end-station
 - 802.1Qca D0.3 comment 61 disposition, with a minor edit:
“Not every node needs to know the ~~scheduling information~~ **explicit route** of every other node.
IS-IS seems to be not the perfect tool for the control of ~~scheduling~~ **explicit routes**.”
- Proof-point for using signaling: RSVP-TE
 - Explicit Routing Object (ERO): list of IP address per hop
 - Uses the RSVP signaling protocol for explicit routing
 - Doesn't necessarily use RSVP reservation
 - DiffServ replaced IntServ (RSVP “Classic”)

Summary of RSVP-TE

- LSP_TUNNEL object contains
 - Destination IP address for session (stream)
 - Tunnel ID: MPLS label-switched path, below IP routing
- EXPLICIT_ROUTE object (ERO) contains a list of

- Address (w/ Prefix Length): Address of router for this hop
- L flag: Is this hop loose or strict?
- RECORD_ROUTE object (RRO): List of actual hops
 - Optional; Detect changes to route by PCE; Detect problems

TSN Addressing

- 802.1 TSN Gen 1 (AVB) uses multicast MAC addresses
- Talker uses multicast MAC address for destination (DA)
 - Analogous to destination IP address / tunnel ID of RSVP-TE
- Each bridge in hop installs DA for forwarding
 - No SPVID or MAC-in-MAC needed by SRP
- No strong argument to change this for TSN Gen 2

Proposed ERO for TSN

| ERO: | Octet # | Name | Comment |
|------|---------|------------------------|--------------------------------------------------------------------|
| | 1-6 | destination_address | Multicast MAC address of ERO; used to bind ERO to single stream |
| | 7-n | one or more ER_address | ER_address = MAC address & flags |

| ER_address: | Octet # | Name | Comment |
|-------------|----------|------------------|---------------------------------------|
| | 1, bit 0 | loose | Loose hop (true) or strict (false)? |
| | 1, bit 1 | start_of_ER_tree | True flags start of new ER_tree |
| | 1, bit 2 | start_of_ER_path | True flags start of new ER_path |
| | 2-7 | MAC_address | Talker, listener, or bridge System ID |

- ER_tree = multicast route from talker to listener(s)
 - One is typical; >1 when redundancy is required; List of ER_path
- ER_path = route from talker to a single listener

Propagation with MSRP

- Use SRP as the signaling protocol for ERO
 - Repeat idea from IETF: Re-use signaling protocol that works
 - SRP works, and we have an open PAR
 - This is not a proposal to literally use RSVP for 802.1 TSN
 - “SRP-TE” described in “Model 2” of
 - <http://www.ieee802.org/1/files/public/docs2012/new-avb-anfredette-srp-spb-v02.pdf>
- New MSRP Attribute Type (e.g. 5): Explicit Route
 - Declare prior to Talker Advertise; DA binds to stream
- Propagation follows MSRP’s context (all Bridge Ports)
 - Initial declaration from anywhere
 - Distinct from reservation

Attribute Value Storage with MSRP

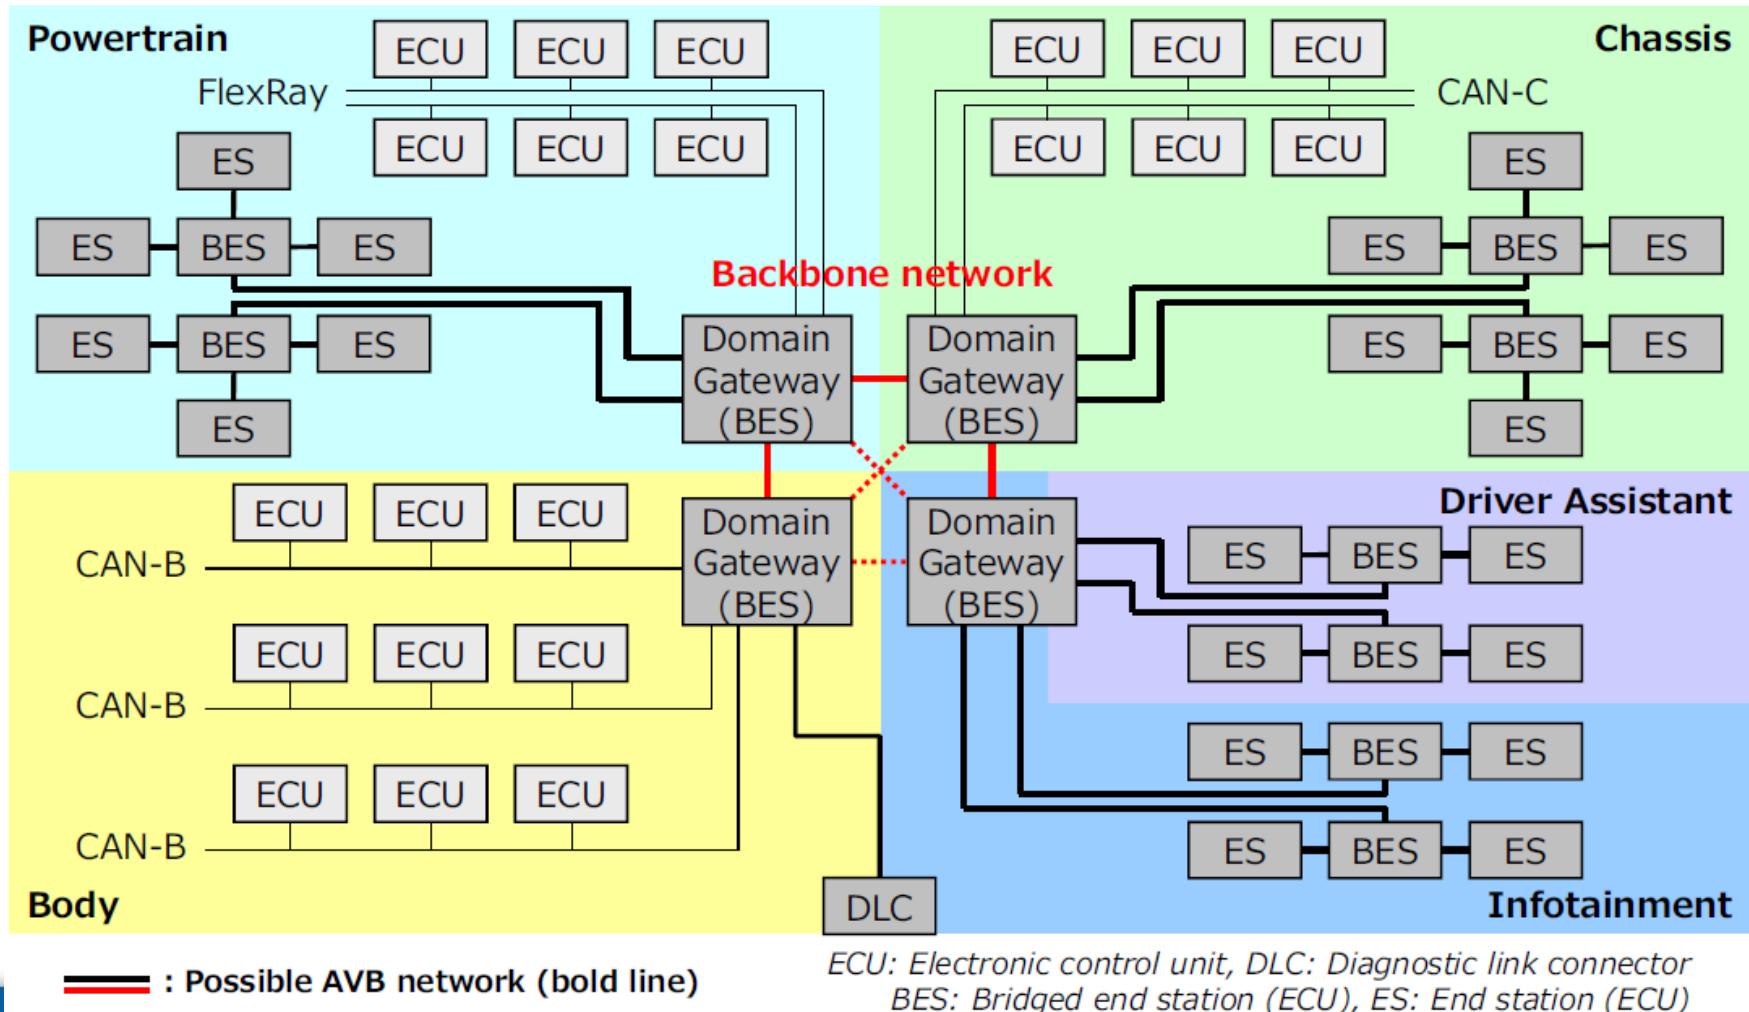

- MRP apps store attribute values to detect changes
- For a bridge, what portion of ERO must be stored?
 - When my System ID is detected...
 - Preceding address tells me the ingress port
 - May be more than one if multiple trees
 - Following address tells me the egress port
 - May be more than one if multiple paths (multiple listeners)
 - I use egress ports to keep forwarding tables up to date
 - All other addresses in paths are irrelevant... no need to store
 - If my System ID is not detected...
 - I am not in the explicit route: Propagate but do not store
- Talker and listeners do not store ERO... route obvious

Record Route (RRO) for TSN?

- When loose hops are used, loops can occur due to transients in implicit routing protocol
 - RSVP-TE RRO along explicit route: Each checks for loops
 - Bad for TSN: Computation everywhere; PCE may not be along route
- 802.1Qca (IS-IS distribution) can solve this for TSN
 - Explicit routes distribute back to PCE
 - PCE detects loop, and uninstalls (leaves) ERO
- Add “Explicit Route” boolean to Talker Advertise
 - Additional error check
 - If true, and ERO not installed, propagate Talker Failed

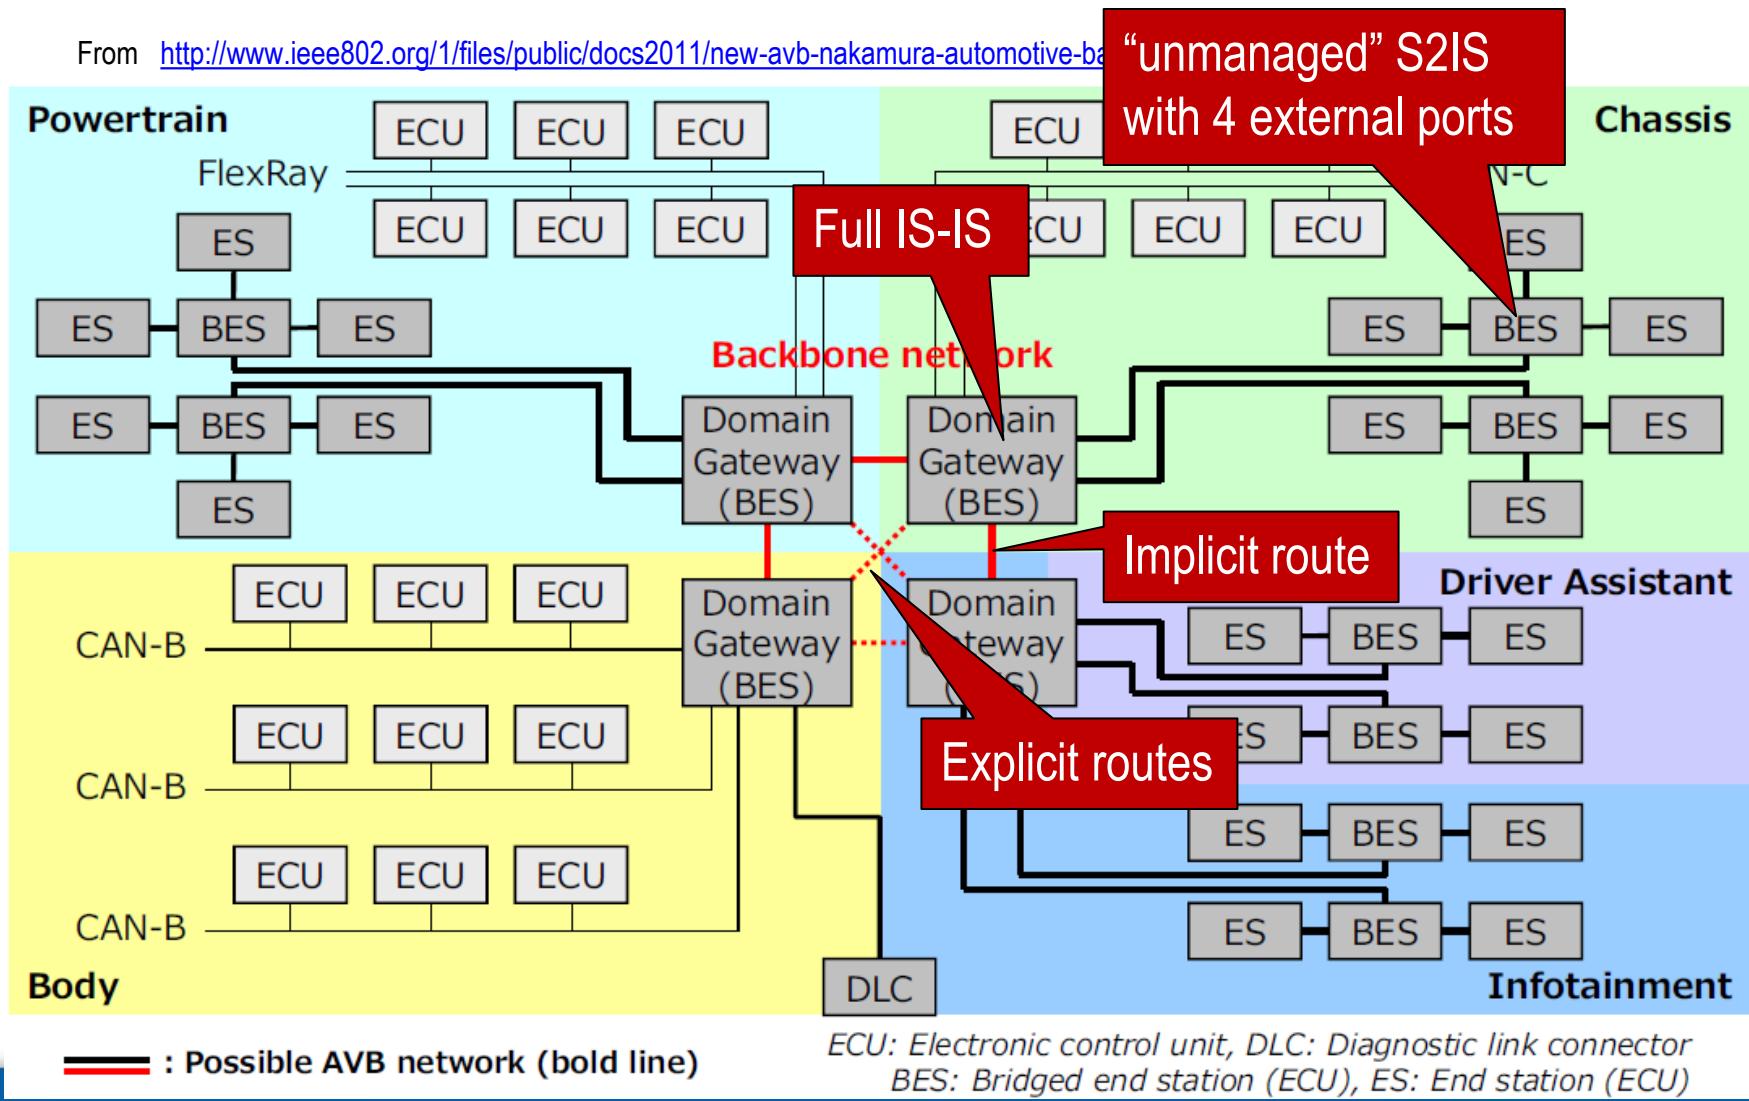

Comparison: Start with Toyota's

From <http://www.ieee802.org/1/files/public/docs2011/new-avb-nakamura-automotive-backbone-requirements-0907-v02.pdf>

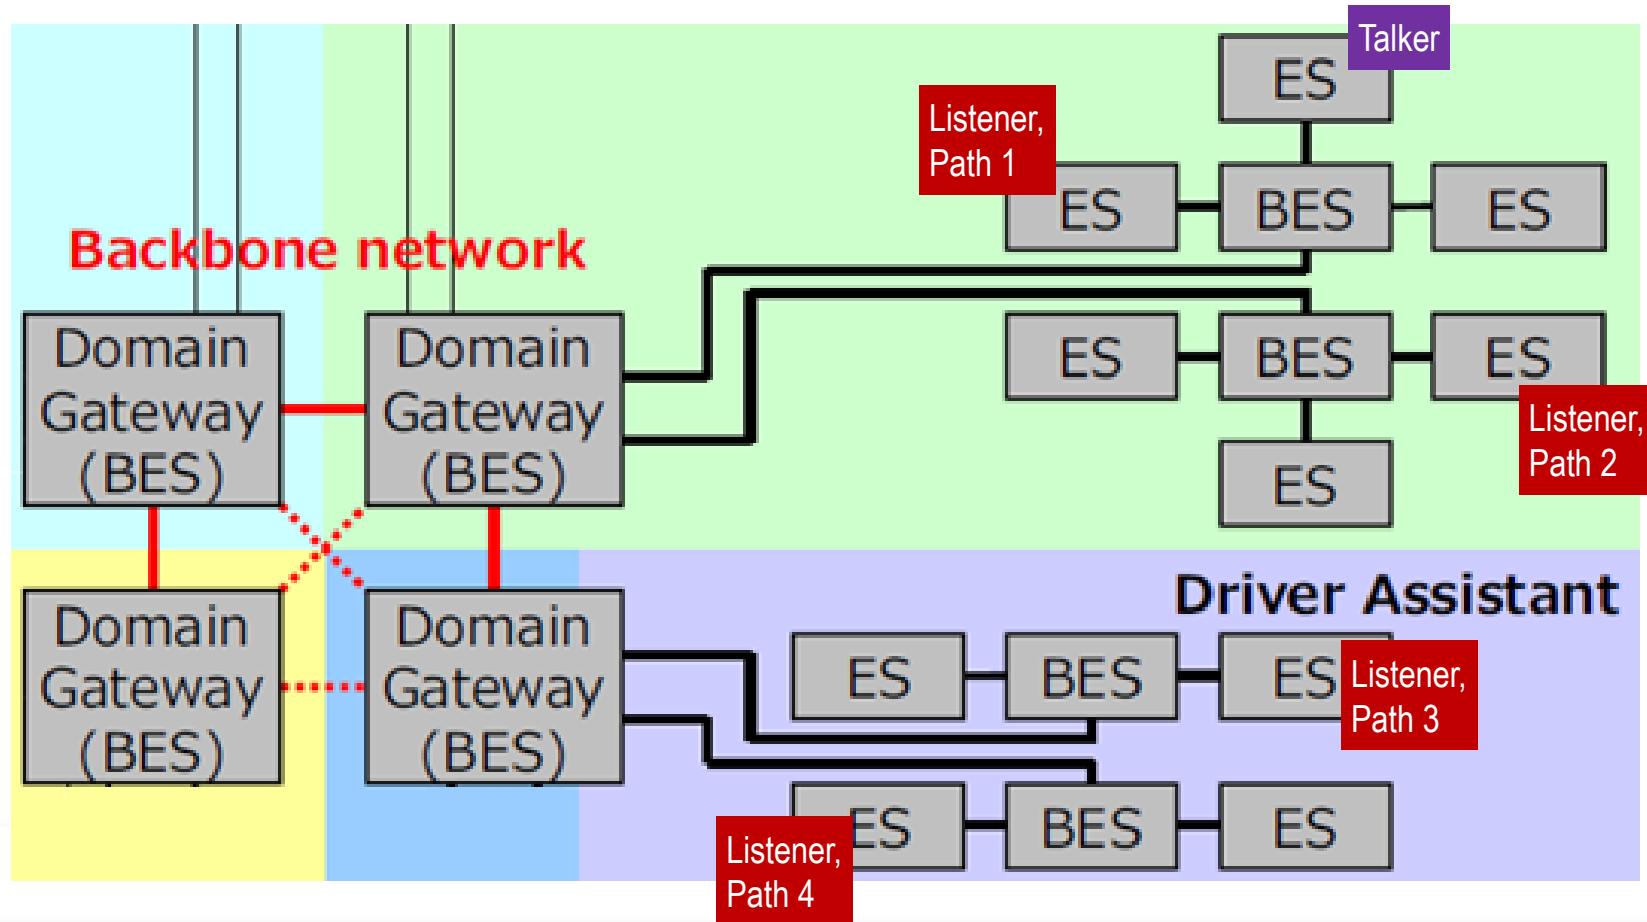

Comparison: Start with Toyota's

From <http://www.ieee802.org/1/files/public/docs2011/new-avb-nakamura-automotive-backbone.pdf>

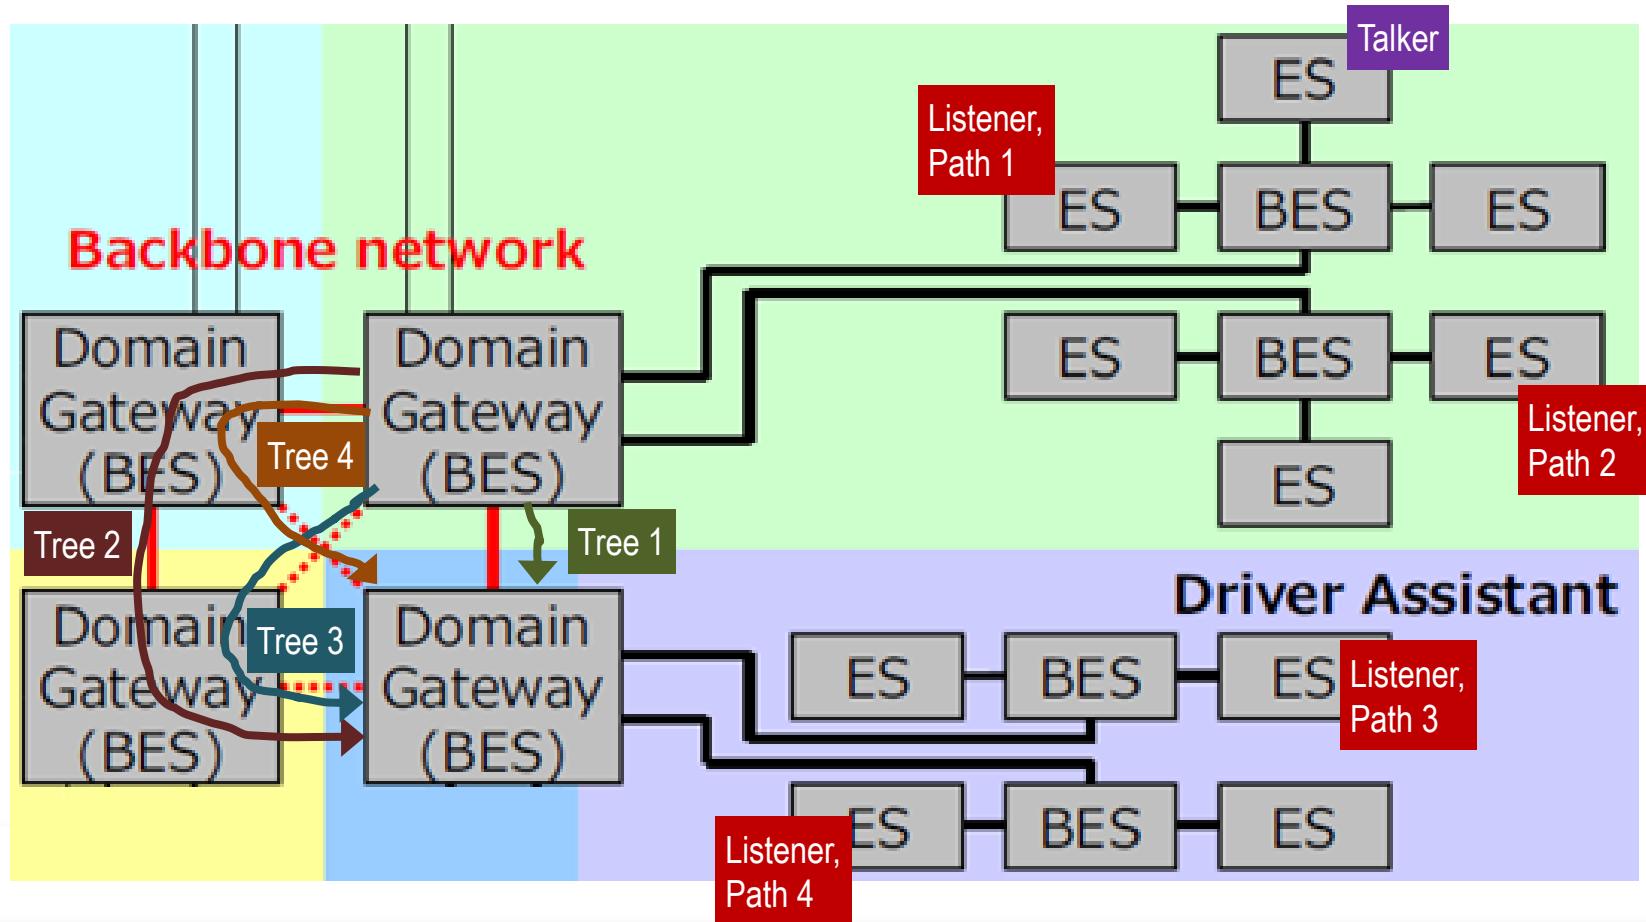

Comparison: Subset for One Stream

- One ES is talker, all other ES shown are listener

Comparison: Subset for One Stream

- One ES is talker, all other ES shown are listener

Comparison: ERO w/ SRP

- BES stores only relevant ER_address (7 bytes each)
- BES near Talker: All trees same, 1 ingress, 2 egress
 - $\text{ERO} = \text{destination (6)} + 7 + 14 = 27 \text{ bytes}$
- Each Domain Gateway stores 4 distinct trees
 - 1 ingress and 1 egress each tree
 - $\text{ERO} = 6 + (4 * 14) = 62 \text{ bytes}$
- BES outside of this subset store nothing
- Total storage required for all ECUs: **335 bytes**
 - $27 + (4 * 62) + (3 * 20)$

Comparison: ERO w/ IS-IS

- Each talker, listener, and bridge stores same database
 - All EROs, each with all trees, each with all paths
- Path 1 = 21 bytes, path 2 = 35, path 3 = 42, path 4 = 42
- Tree 1 = 140 bytes, tree 2 = 154 (+14 for 2 extra hops), tree 3 = 147, tree 4 = 147
- Plus 6 bytes for destination = ERO of 594 bytes
- 13 ECUs are in explicit route, but 33 ECUs overall
 - Every ECU must store the ERO, even if not in the route
- Total storage required for all ECUs: **19602 bytes**
 - $33 * 594$; approximately 58 times more than SRP

PCE Workflow for ER: (Repeat)

| Step | Typical IETF | Proposal for TSN |
|-------------------------------------------------------------|---------------------------------|-----------------------------------|
| 1. Implicit routes | Mixed (IGP like IS-IS, or OSPF) | Mixed (STP like ISIS-SPB or MSTP) |
| 2. PCE learns topology and metrics | Mixed (ISIS-TE, OSPF-TE, ...) | 802.1Qca (IS-IS) |
| 3. PCE performs calculation | (not standardized by IETF) | (not standardized by 802.1) |
| 4. PCE installs explicit routes into IS (bridges / routers) | RSVP-TE | Extensions to SRP (SRP-TE) |
| 5. Bandwidth / stream reservation over explicit routes | DiffServ | SRP |
