6 Abstract

7

8 This document describes a selection of cut-through related mechanisms in order to support
9 the implementation of traffic classes that need short latency requirements over a relatively
10 large number of hops.

11

12 Its intended to use and extend the forwarding process from IEEE 802.1Q.

32 2 Cut-through needs in Industrial Automation

33 2.1 Introduction

34

35 Ethernet TSN shall cover the requirements of the existing and future industrial automation systems.

36 The data delivery guaranties for the isochronous traffic require lower latency than IEEE 802.1Q
37 standard “store and forward” network infrastructure may be able to provide. In order to the fulfill
38 these requirements different Vendor and/or System-Provider specific solutions are developed by
39 using the mechanism referred as Cut-through switching.

40 In the course of the IEEE 60802 or the IEC this mechanism shall be standardized for bridges as
41 this mechanism is necessary to fulfill the industrial automation use cases.

42

43 2.2 CT – requirements

44

45 An IEC/IEEE 60802 bridge:

- 46 • Shall provide the capability for cut through per input port and per output queue
- 47 • Shall be configurable which queues can use the cut-through forwarding mechanisms
- 48 • Shall report the cut-through delays through the management protocol. This information shall
49 be available in the data sheet. independentDelayMin and independentDelayMax shall be
50 used to identify the cut-through delays.
- 51 • Shall support existing mechanism for handling of erroneous long frames which are
52 forwarded as CT frames, too. Faulty cut-through traffic (erroneous long frames) shall be
53 shortened when being forwarded and thus, removed over time to limit the occupied
54 bandwidth on the path of the CT frames.
- 55 • Shall handle a Cut-through frame during the forwarding process with the same rules as a
56 Store-Forward (SF) frame, including policing, forwarding decisions and VLANs.
- 57 • Shall support CT for peer to peer links from 10 Mbps to 2,5 Gbps
- 58 • Shall show no other externally observable difference between SF and CT (besides the
59 stated ones) than a shorter latency and possible forwarding of CRC errored frames.

60

61 2.3 CT – proposed solution

62

63 *Today:* IEEE standard specifies that the switch starts the forwarding process after a frame is
64 completely received and validated.

65 *Tomorrow:*

66 The forwarding process may start after the reception of the first 64 bytes (configurable) are
67 received. Because of such a forwarding process, a frame that is not completely received
68 may be put on the transmit queue and can be used by the transmission selection.

69 In addition, it is required to specify a method for invalidating the frame transmission as soon
70 as an error is detected with the goal to shorten the frame as much as possible. Thus, invalid
71 frame fragments should be shortened as much as possible by each hop and be removed by

- 72 the hop as soon as the remaining frames size is shorter than MinFrameSize to avoid
73 “circulating frame fragments”.
- 74 If the bridge operating in cut-through already started forwarding and detects that the frame
75 is damaged or truncated, it shall append the error sequence foreseen in IEEE 802-3:2018,
76 27.3.1.2.2 and then stop further transmission of that frame.
- 77 All other 802.1Q existing mechanisms will still work, but an additional “late” error handling
78 mechanism is needed for “late” error detected frame underrun, invalid frame and incorrect
79 frame.
- 80 The cut-through support is implemented per queue, and it can be configurable which
81 queues can use the cut-through forwarding mechanisms. This influences the transmission
82 selection
- 83 • if CT is activated the transmission selection will start the forwarding process as soon
84 as a frame descriptor is assigned to a queue.
 - 85 • if deactivated, the transmission selection will start the forwarding process as soon as
86 a frame descriptor is assigned to a queue and the frame is completely received by
87 the switch.
- 88
- 89 Before starting CT forwarding, it shall be checked that the Qbv gate is open for a specific
90 queue at least for queueMaxSDU (see 802.1Qbv). If a received frame is detected oversize
91 (> queueMaxSDU) after forwarding has started, the forwarded frame shall be truncated on
92 egress to queueMaxSDU size and no valid CRC shall be added.
- 93
- 94 First CT fragments (smaller is better):
- 95 • 32 bytes (supported by some of the todays vendor specific implementations)
 - 96 • 64 bytes (mandatory)
 - 97 • 128 bytes
- 98
- 99 Shortening by each hop (more is better):
- 100 • 8 bytes (mandatory)
 - 101 • 16 bytes (supported by some of the todays vendor specific implementations)
 - 102 • 32 bytes
- 103
- 104 Frame handling in case of shortening (IEEE 802-3:2018, 27.3.1.2.2):
- 105 • Support TX_ER to invalid the frame
 - 106 • Offer byte-granular shortening
 - 107 • Adding Error Code
 - 108 • for 10Mbps/100Mbps:
109 1-3 Error-Code Nibble, Frame will be shipped with unearthed nibble number!
 - 110 • for 1Gbps:
111 2 Error-Code Nibble, Frame will be shipped with even nibble count!

- 112 • for <10Gbps:
113 ??? Error-Code Nibble, Frame will be shipped with even nibble count!

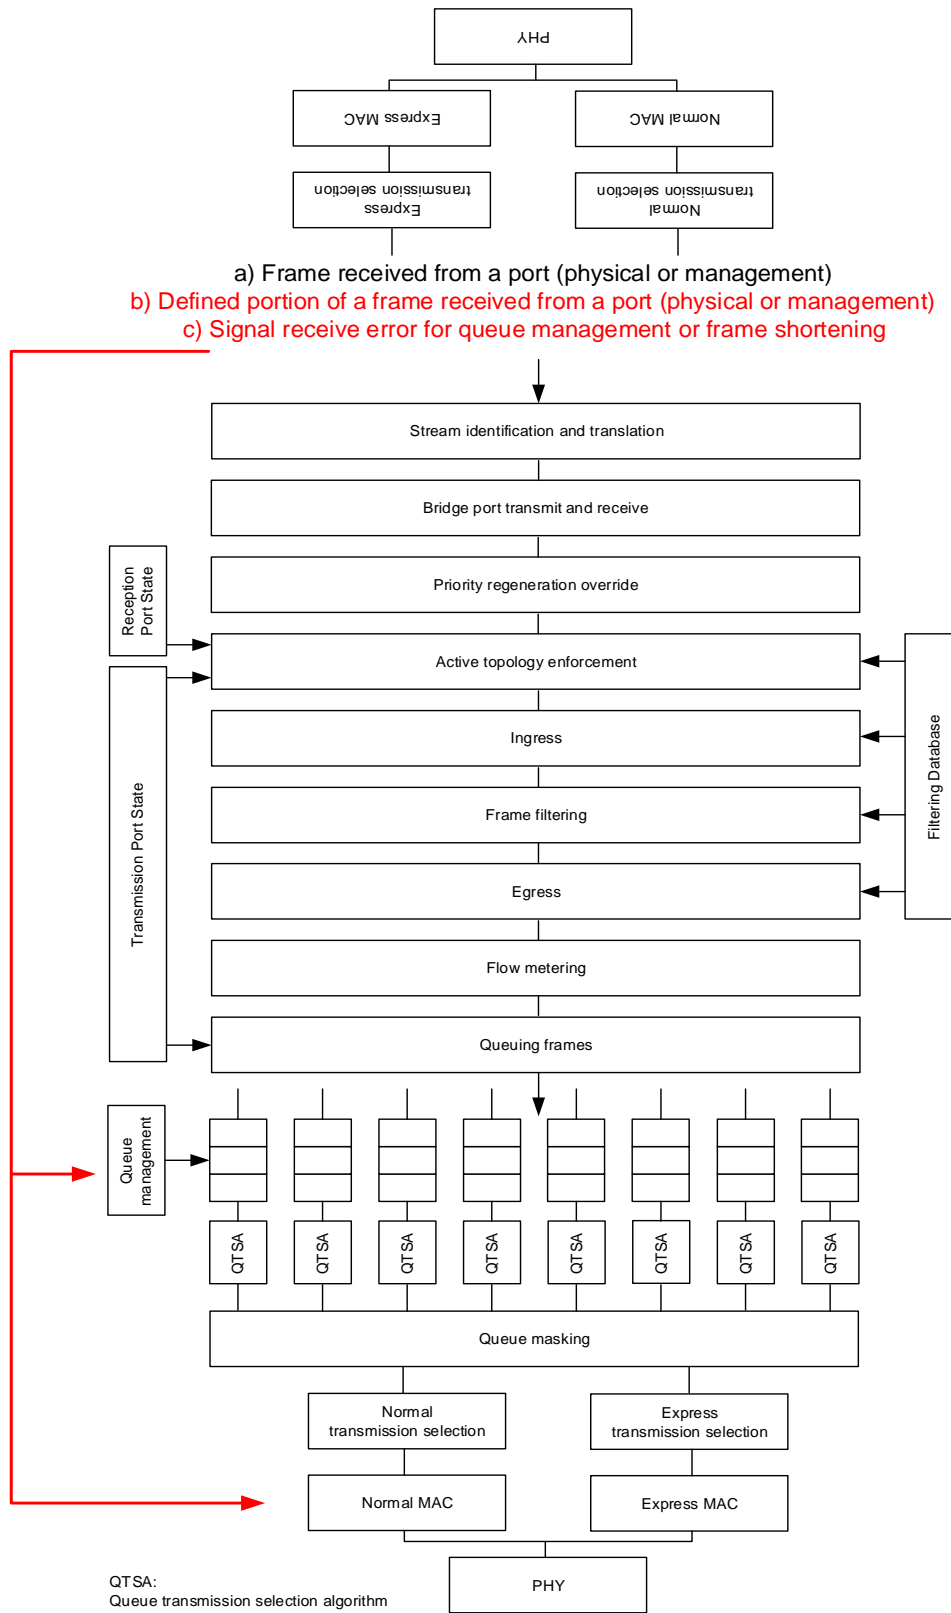

114

115 **2.4 CT - Integration model**

116

117 Figure 1 shows in principle the needed extensions to the existing IEEE 802.1Q forwarding model.
