19 **14.23 Fault Tolerant Timing Module System Parameter Data Set (fttmSystemDS)**

20 **14.23.1 General**

21 **< The list below consists of initial ideas of potential FTTM managed objects. More thought and discussion**  
22 **is needed.>**

23 **14.23.2 fttmNumTimeIndexes (UInteger8)**

24 The parameter fttmNumTimeIndexes is equal to the number of input ClockTarget Interfaces connected to  
25 the FTTM.

1 **14.23.3 fttmNumDTsAs (UInteger8)**

2 The parameter fttmNumDTsAs is equal to the number of DTSA instances in the FTTM.

3 **14.23.4 fttmNumDTsATimeIndexes[n] (Vector of UInteger8)**

4 The parameter fttmNumDTsATimeIndexes[n] is the number of input ClockTarget Interfaces connected to  
5 DTSA Instance x.

6 **14.23.5 fttmDTsATimeIndexMap[fttmNumDTsAs][fttmNumDTsATimeIndexes]**

7 The parameter fttmDTsATimeIndexMap[x][y] maps the FTTM's input ClockTarget interfaces to DTSA  
8 instances' input ClockTarget interfaces, where appropriate.

9 **14.23.6 fttmNumITSATimeIndexes (Vector of UInteger8)**

10 The parameter fttmNumITSATimeIndexes is the number of input ClockTarget Interfaces on the ITSA  
11 Instance.

12 **14.23.7 fttmITSAMap[fttmNumITSATimeIndexes]**

13 The parameter fttmItsAMap maps either a FTTM's input ClockTarget interface or a DTSA output  
14 ClockTarget interface is each of the ITSA's input ClockTarget interfaces.

21 **18. Hot Standby**

22

1 **19. Fault-tolerant timing with time integrity**

2 **19.1 General**

3 It is important for some time-sensitive applications (e.g., aerospace networks, per IEEE P802.1DP) to  
4 consider fault tolerance, including availability and integrity of the synchronizing function, to provide  
5 reliable and trustworthy system behavior. Features of gPTP that can be used to support fault-tolerant time  
6 synchronization include its provisions for multiple time domains, multiple GMs, multiple time distribution  
7 paths, and multiple gPTP instances per port in Bridges and end stations, and the external port configuration  
8 mode (see 10.3.1.3) that allows static time distribution paths to be established. The use of these features  
9 must be carefully considered by a system designer to ensure that the application’s requirements for assured  
10 systems are met. For example, an aerospace network is typically expected to tolerate multiple (typically 2)  
11 simultaneous arbitrary faults in Bridges, end stations, links, and GMs to maintain availability and integrity  
12 of clock synchronization.

13 To achieve fault-tolerant timing with time integrity, this standard defines a Fault-Tolerant Timing Module  
14 (FTTM) for use with the fault tolerance supporting gPTP features listed above. The concepts used by the  
15 FTTM are described in 19.2. Details on the FTTM and its default operations are given in 19.3. General  
16 information about fault-tolerant timing with time integrity can be found in Annex J.

17 **19.2 Fault-tolerant time synchronization concepts**

18 **19.2.1 Availability of time**

19 The continuous availability of time is enhanced by redundancy. For gPTP, this redundancy can be  
20 implemented by using multiple time domains, multiple time distribution paths, and multiple gPTP instances  
21 in Bridges and end stations.

22 **19.2.2 Trust and Integrity of time**

23 For this standard, a trusted time is one that passes a specified criterion that identifies it as being within a  
24 safe bound of a non-faulty time and is, thus, safe to use. This establishment of trust gives integrity to the  
25 time.

26 For gPTP, trust, and hence integrity, can be established through the comparison of the times coming from  
27 independent time sources and the observation that they match within the specified criterion. See 19.2.7.4  
28 for an example of such a criterion.

29 **19.2.3 Time agreement generation and preservation**

30 Time agreement generation and preservation is the process by which multiple time source nodes (GMs)  
31 come to an agreement on the time and maintain that agreement in the presence of both faults and oscillator  
32 drift. This process preserves both the collective accuracy and relative precision of the set of GMs.

33 Time agreement generation and preservation is outside the scope of this standard.

1 **19.2.4 Time agreement distribution**

2 Time agreement distribution is the process of distributing the time established by time agreement  
3 generation from time source nodes (GMs) to time destination nodes (gPTP End Instances). Time agreement  
4 distribution is performed using gPTP, per the models described in clause 7 and the mechanisms specified in  
5 clauses 8 to 16 of this standard.

6 **19.2.5 Dependent gPTP times**

7 Dependent gPTP times share one or more common time source components. This could be a common GM,  
8 continuously synchronized GMs, GMs that share a common (continuously connected) ClockSource, or a  
9 common gPTP Relay Instance.

10 Because dependent gPTP times share one or more common influencers, they do not, on their own, enable  
11 end-to-end integrity checking of the time synchronization function. However, they can be used to improve  
12 the availability of a given time source and can provide partial integrity checks. For example, an application  
13 that receives timing from a single GM through more than one redundant synchronization trees has  
14 increased availability of that GM's time and can check the integrity of the synchronization trees by  
15 comparing the time received from them. However, because the time originates from a single GM, the  
16 integrity of that GM's time cannot be confirmed and, thus, end-to-end integrity of the time synchronization  
17 function is not achieved.

18 When a set of dependent gPTP times is used in combination with other gPTP times, which are independent  
19 (see 19.2.6), the set of dependent gPTP times can be reduced to a single independent gPTP time and used to  
20 enhance the ability to achieve end-to-end integrity of the time synchronization function. This operation is  
21 performed by the Fault-Tolerant Timing Module (see 19.3).

22 Dependent gPTP times can be identified by one of the following methods:

- 23 — They have the same gPTP domainNumber, majorSdoID, and minorSdoID. This indicates that gPTP  
24 messages from the same gPTP GM are received by two gPTP End Instances, on two distinct  
25 physical ports, that are serviced by the FTTM.
- 26 — They have different gPTP domainNumbers but the same gmtimeBaseIndicator. This indicates that  
27 the gPTP messages come from different gPTP GMs that share the same clockSource.
- 28 — They have gPTP domainNumbers that are defined by a management entity, which is out of scope of  
29 this standard, to be dependent.

30 NOTE—Faults that cause the masquerading of any of the above gPTP fields can be mitigated by the Fault-Tolerant  
31 Timing Module (see 19.3).

32

33 In a network that supports fault-tolerant timing with time integrity, the gmTimeBaseIndicator shall be  
34 unique across all ClockSources.

35 NOTE—A network management entity (outside the scope of this standard) could be used to ensure that  
36 gmtimeBaseIndicator is unique across all clock sources present.

1 **19.2.6 Independent gPTP times**

2 Independent gPTP times do not share any common time source components with each other and, therefore,  
 3 deliver independent time values. Independent gPTP times are, by definition, from different domains.

4 Because independent gPTP times do not share any common influencers, they can enable end-to-end  
 5 integrity checking of the time synchronization function, provided their times track sufficiently closely.  
 6 Independent gPTP domains need to be aligned to each other in a manner that is resilient to faults (i.e.,  
 7 achieve time agreement and preservation, see 19.2.3), including Byzantine faults. For example, time  
 8 agreement mechanisms can be used to align the clocks of two independent GMs.

9 Because the independent gPTP domains are synchronized to each other, they provide a redundant source of  
 10 time to the end application and, thus, also improve the availability of the time synchronization function to  
 11 the end application.

12 **19.2.7 Time error accumulation**

13 As gPTP time is distributed through a network from a GM to a gPTP End Instance, time error accumulates  
 14 due to the following reasons:

- 15 — Timing errors at the GM (TE<sub>Gm</sub>)
- 16 — Timing errors at intermediate gPTP Relay Instances (TE<sub>Rly</sub>)
- 17 — Timing errors at the gPTP End Instance (TE<sub>End</sub>)
- 18 — Link asymmetry between gPTP Instances (TE<sub>Ink</sub>)

19 The above time errors are illustrated in Figure 1.

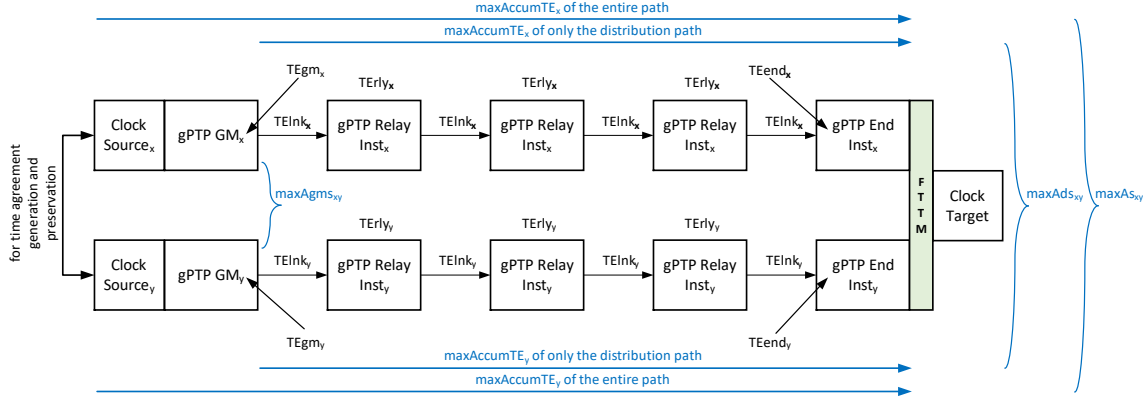

20  
 21 **Figure 1—Time error accumulation across a network**

22 It is possible to determine the potential maximum absolute value of each of the above time errors and, thus,  
 23 the maximum potential time error at the gPTP End Instance. This result, maxAccumTE (see 19.2.7.1), if  
 24 available, can be used by the FTTM to select the best gPTP time to present to the ClockTarget.

25 NOTE— The potential maximum absolute values of TE<sub>Gm</sub>, TE<sub>Rly</sub>, TE<sub>End</sub>, and TE<sub>Ink</sub> are expected to be calculated or  
 26 measured prior to operational usage. This could be done at the design, characterization, or certification phase. The  
 27 specific methods and procedures to do this are not defined in this standard.

28 The ENHANCED\_ACCURACY\_METRICS TLV from IEEE Std 1588a-2023 can be used to accumulate  
 29 the maximum constant and dynamic time errors of each gPTP instance and the connecting links, on a hop-  
 30 by-hop basis, in the path from the GM to, but not including, the final gPTP End Instance. This TLV is  
 31 carried in gPTP Announce messages.

**Figure 2—Time skew across two time distribution paths**

Time skew between two time distribution paths is shown in Figure 2. The time error contributors across each path are the same as shown in Figure 1, but the contributors on each path are marked with the path's identifying suffix, x or y.

The various time skew results are described in 19.2.7.1, 19.2.7.2, 19.2.7.3, and 19.2.7.4.

### 19.2.7.1 maxAccumTE<sub>x</sub>

The parameter maxAccumTE<sub>x</sub> is the maximum non-faulty accumulated time error magnitude for the time distributed on path x, from its GM (TEgm), through all intermediate gPTP Relay Instances (TEerly) and the corresponding links (TEInk), to the gPTP End Instance (TEend) that is connected to the FTTM.

$$\text{maxAccumTE}_x = \max(|\text{TEgm}_x|) + \sum \max(|\text{TEerly}_x|) + \sum \max(|\text{TEInk}_x|) + \max(|\text{TEend}_x|)$$

where  $\sum$  is the summation symbol and represents a summation of all instances of the term adjacent to it

### 19.2.7.2 maxAgms<sub>xy</sub>

The parameter maxAgms<sub>xy</sub> is the maximum accepted time skew magnitude between two non-faulty gPTP GMs, GM<sub>x</sub> and GM<sub>y</sub>. This value is equal to the worst-case time error magnitude between the two GMs when they are not faulty.

$$\text{maxAgms}_{xy} = \max(|\text{TEgm}_x|) + \max(|\text{TEgm}_y|)$$

### 19.2.7.3 maxAds<sub>xy</sub>

The parameter maxAds<sub>xy</sub> is the maximum accepted distribution skew magnitude between the time of two non-faulty times, distributed on path x and path y. This value is equal to the worst-case time error magnitude between the two times, from the perspective of the FTTM, resulting from their distribution paths when they are not faulty.

$$\text{maxAds}_{xy} = \sum \max(|\text{TEerly}_x|) + \sum \max(|\text{TEInk}_x|) + \max(|\text{TEend}_x|) + \sum \max(|\text{TEerly}_y|) + \sum \max(|\text{TEInk}_y|) + \max(|\text{TEend}_y|)$$

### 19.2.7.4 maxAs<sub>xy</sub>

The parameter maxAs<sub>xy</sub> is the maximum accepted skew magnitude between two non-faulty times, distributed on path x and path y. This value is equal to the worst-case time error magnitude between two

1 synchronized times, from the perspective of the FTTM, when they are not faulty. This value can be used as  
 2 a criterion to determine the trustworthiness of the times being compared.

$$\begin{aligned}
 3 \quad \max A_{s_{xy}} &= \max A_{gms_{xy}} + \max A_{ds_{xy}} \\
 4 \quad &= \max AccumTE_x + \max AccumTE_y
 \end{aligned}$$

5 System integrators should design their TSN network, which supports fault-tolerant timing and time  
 6 integrity, such that synchronization-dependent nodes can withstand a drift equal to the magnitude of this  
 7 maximum accepted skew.

### 8 **19.3 Fault-Tolerant Timing Module**

9 To enable fault-tolerant timing with time integrity, a Fault-Tolerant Timing Module (FTTM) operating at  
 10 the application layer, per Clause 9, is to be implemented in all time-aware bridges and end stations that  
 11 receive multiple gPTP times. The FTTM manages the selection of a time source from amongst two or more  
 12 gPTP times (and gPTP instances) to support increased availability (see 19.2.1) and integrity (see 19.2.2).  
 13 The FTTM also supports single domain solutions but, in this scenario, it does not provide any  
 14 enhancements for increased availability or integrity.

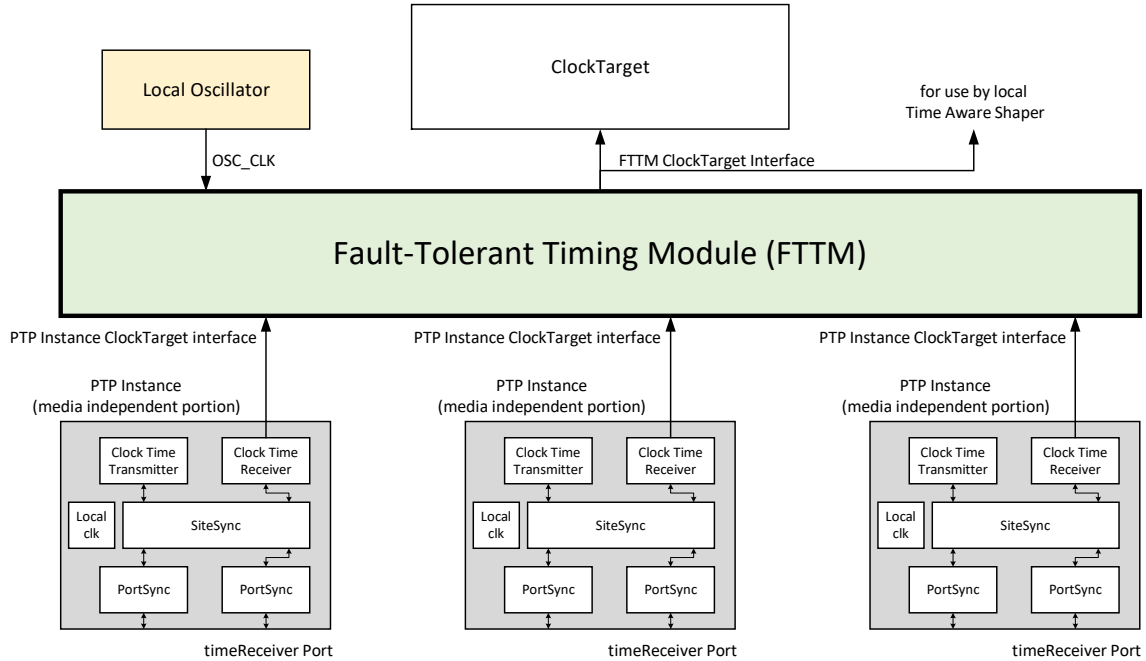

15 The availability and integrity scenarios supported by the FTTM are listed below.

- 16 — Enhanced availability and integrity scenario:  
 17 This scenario operates with multiple times and multiple domains.  
 18 In this mode, the FTTM supports increased availability and integrity.
- 19 — Enhanced availability and limited integrity scenario:  
 20 This scenario operates with multiple times and a single domain.  
 21 In this mode, the FTTM supports increased availability and potential time distribution integrity, but  
 22 not GM integrity.
- 23 — Regular availability and no integrity scenario:  
 24 This scenario operates with a single time and, hence, a single domain.  
 25 In this mode, the FTTM does not support increased availability or integrity.

26 Figure 3 illustrates the FTTM operating with three gPTP instances. The FTTM can also use the local  
 27 oscillator’s clock (OSC\_CLK) as an input to its selection algorithm.

28 Because the FTTM resides between gPTP Instances and a ClockTarget, its effect is localized. This allows  
 29 different algorithms, each of which specifically serves the timing requirements of the corresponding  
 30 ClockTarget, to be used by each FTTM. The default algorithms for the FTTM are defined in 19.3.3.

31

**Figure 3— Fault-Tolerant Timing Module in operation**

**19.3.1 Scope and assumptions**

The following list provides the detailed assumptions and goals for the FTTM:

- A fault-tolerant network (with time integrity) and its configuration are static during normal operation.
- All gPTP ports are configured using the external port configuration provision (i.e., the BTCA is not used).
- There is no administrative reconfiguration during run-time in the event of faults.
- While one time and one domain is supported by the FTTM, more than one time and more than one domain is required to enable fault tolerant timing with time integrity. To support interoperability, a minimum number of times and domains needs to be specified for an application.
- gPTP times are recognized as being dependent or independent as defined in clause 19.2.5 and 19.2.6, respectively.

**19.3.2 Functional description**

The FTTM shall consist of the following functions:

- A local oscillator clock (OSC\_CLK).
- ClockTarget application interfaces (see clause 9) providing time information to the FTTM, where gPTP End Instances serve as the ClockTimeReceiver entities and the FTTM serves as the

- 1           ClockTarget entity. Time is passed to the FTTM via each ClockTarget application interface's  
2           timeReceiverTimeCallback parameter.
- 3       — Zero or more instances of a Dependent Time Selection Algorithm (DTSA).
  - 4       — Zero or more instances of ClockTarget application interface(s) (see clause 9) providing time  
5           information from DTSA(s) to the ITSA, where each DTSA serves as a ClockTimeReceiver entity  
6           and the ITSA serves as a ClockTarget entity. Time is passed to the ITSA via each ClockTarget  
7           application interface's timeReceiverTimeCallback parameter.
  - 8       — One instance of an Independent Time Selection Algorithm (ITSA).
  - 9       — ClockTarget application interface(s) (see clause 9) providing time information from the FTTM,  
10           where the FTTM's output (FTTM\_OUTPUT) serves as the ClockTimeReceiver entity to the  
11           application's ClockTarget entity. Time is passed to the application's ClockTarget entity via the  
12           ClockTarget application interface's timeReceiverTimeCallback parameter.
- 13   A functional block diagram of the FTTM is shown in Figure 4.

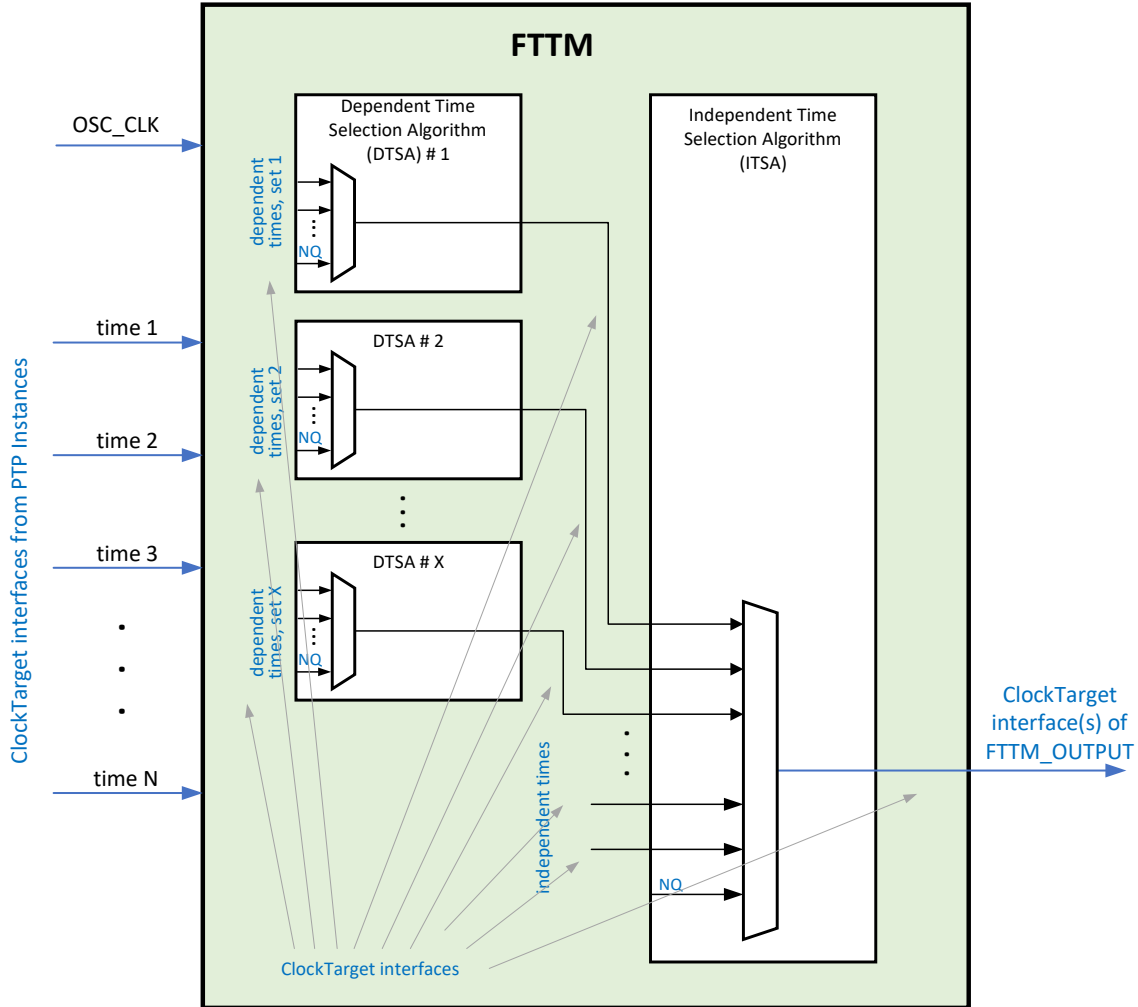

Figure 4—FTTM functional block diagram

1  
2  
3

4 **19.3.2.1 Input ClockTarget interfaces**

5 The ClockTarget interfaces that pass time information from the gPTP End Instances to the FTTM are  
6 designated as, from the FTTM’s perspective, input ClockTarget interfaces. They may be any of the  
7 following types defined in clause 9, ClockTargetEventCapture, ClockTargetTriggerGenerate, and  
8 ClockTargetClockGenerator, or they may be of another type. However, they should all be of the same type.  
9 The ClockTargetPhaseDiscontinuity interface should also be provided by the gPTP End Instances to the  
10 FTTM.

11 The FTTM’s input ClockTarget interfaces can be for times that have a dependency with one or more times  
12 of other input ClockTarget interfaces or can be for times that have no dependency with the times of other  
13 input ClockTarget interfaces.

14 **19.3.2.2 DTSA and ITSA**

15 The DTSA and the ITSA each analyze their own set of input ClockTarget interfaces and, based on a  
16 specified criteria (e.g., see 19.2.7.4, 19.2.5, 19.2.6 for examples), determine which corresponding time(s)  
17 can be trusted (see 19.2.2). Being trusted does not mean the time is definitely non-faulty. However, as long

1 as a time remains trusted (i.e., as long as its time continues to pass the specified criteria), it can be safely  
2 used by the DTSA or ITSA.

3 Any time that has an isSynced status (see 18.4.1.1) equal to FALSE or a gmPresent status (see 10.2.4.13)  
4 equal to FALSE shall be declared to be untrusted. Other conditions for determining whether a time is  
5 trusted are determined by the specified criterion.

#### 6 **19.3.2.2.1 DTSA**

7 Each set of input ClockTarget interfaces that share a common dependency shall be processed as a group by  
8 one instance of the DTSA. This grouping allows each DTSA instance to produce an output that is  
9 independent from the outputs of the other DTSA's and from the other ClockTarget interfaces that are  
10 connected as inputs to the ITSA.

11 Each instance of the DTSA shall select one of its input times, or the Not Qualified (NQ) time (see  
12 19.3.2.2.3) if none of its input times can be determined to be trusted, as its result. The selected time's  
13 ClockTarget interface is passed to the output of the DTSA. This output is passed to the ITSA as an  
14 independent time.

15 The default DTSA is described in 19.3.3.3. Other algorithms for the DTSA may also be used by the FTTM.  
16 Other algorithms for the DTSA are not required to produce the same result as the default DTSA to achieve  
17 time convergence.

#### 18 **19.3.2.2.2 ITSA**

19 When operating in the enhanced availability and integrity scenario (see 19.3), the set of input ClockTarget  
20 interfaces that share no dependency with each other, which include the output ClockTarget interfaces of all  
21 instances of the DTSA, shall be processed by the ITSA. The ITSA shall select one of its input times, or the  
22 NQ time if none of its input times can be determined to be trusted, as its result.

23 When operating in the enhanced availability and limited integrity scenario (see 19.3), it is expected that all  
24 the input times to the FTTM are connected to the ITSA regardless of their independence from each other  
25 (i.e., DTSA's are not used in this scenario). The ITSA shall select one of its input times, or the NQ time if  
26 none of its input times can be determined to be trusted, as its result.

27 When operating in the regular availability and no integrity scenario, (see 19.3), the ITSA receives the sole  
28 input time to the FTTM. In this special scenario, the ITSA shall always select the sole input time as its  
29 result.

30 The FTTM's local oscillator clock, OSC\_CLK, may be used by the ITSA as a frequency reference to infer  
31 additional information about the qualities of the input times.

32 The selected time's ClockTarget interface shall be passed to the output of the ITSA and becomes the output  
33 of the FTTM, FTTM\_OUTPUT. This output is passed to the application ClockTarget entity.

34 The default ITSA is described in 19.3.3.4. Other algorithms for the ITSA may also be used by the FTTM.  
35 Other algorithms for the ITSA are not required to produce the same result as the default ITSA to achieve  
36 time convergence.

#### 37 **19.3.2.2.3 Not Qualified (NQ) time**

38 The Not Qualified (NQ) time is used to represent the condition where none of the input times to the DTSA  
39 or to the ITSA can be determined to be trusted. The NQ time contains the ClockTarget interface from any  
40 one of the input times (arbitrarily selected or implementation specific) being processed by the algorithm but

1 shall have the isSynced status (per P802.3ASdm) and the gmPresent status forced to FALSE, to indicate the  
2 untrusted condition.

3 NOTE—Because the NQ time is, by definition, not trusted, the values of its other parameters (aside from  
4 isSynced and gmPresent ) have no functional impact.

5 All the possible parameters in the NQ time are listed below.

6 — domainNumber = the domainNumber from the arbitrarily selected time from the set of input times  
7 being processed by the algorithm

8 — timeReceiverTimeCallback = the timeReceiverTimeCallback value from the arbitrarily selected  
9 time

10 — isSynced = FALSE

11 — gmPresent = FALSE

12 — errorCondition = the errorCondition value from the arbitrarily selected time

13 — clockPeriod = the clockPeriod value from the arbitrarily selected time

14 — timeReceiverCallbackPhase = the timeReceiverCallbackPhase value invoked by the ClockTarget  
15 entity of the ClockTarget interface

16 — grandmasterIdentity = the grandmasterIdentity value from the arbitrarily selected time

17 — gmTimeBaseIndicator = the gmTimeBaseIndicator value from the arbitrarily selected time

18 — lastGmPhaseChange = the lastGmPhaseChange value from the arbitrarily selected time

19 — lastGmFreqChange = the lastGmFreqChange value from the arbitrarily selected time

### 20 **19.3.2.3 Output ClockTarget Interfaces**

21 The ClockTarget interfaces that pass time information from the FTTM to the application’s ClockTarget  
22 entity are designated as, from the FTTM’s perspective, output ClockTarget interfaces. They may be any of  
23 the following types defined in clause 9, ClockTargetEventCapture, ClockTargetTriggerGenerate, and  
24 ClockTargetClockGenerator, or they may be of another type. However, they should be consistent with the  
25 types on the FTTM’s input ClockTarget interfaces. all be of the same type. The  
26 ClockTargetPhaseDiscontinuity interface should also be provided by the FTTM to the application’s  
27 ClockTarget entity.

### 28 **19.3.3 Default Operations**

#### 29 **19.3.3.1 General**

30 The default DTSA state machine, the default ITSA state machine, and the default selection process used by  
31 both state machines are defined in this subclause.

32 Subclause 19.3.3.2 describes the default selection process, with its variables and pseudo-code.

33 Subclause 19.3.3.3 describes the default DTSA state machine, with its variables and its state diagram.

34 Subclause 19.3.3.4 describes the default ITSA state-machine, with its variables and its state diagram.

1

2 **19.3.3.2 Mid-value time-index selection process**

3 The mid-value trusted time-index selection process (MVTISP) determines which time indexes have trusted  
 4 times and then finds, amongst these time indexes with trusted times, the time index with the median time.  
 5 The MVTISP shall be used by the default DTSA and by the default ITSA.

6 The MVTISP looks at all possible combinations of input time index pairs to determine which pairs satisfy  
 7 their specified maximum accepted skew magnitude threshold,  $\max AS_{xy}$  (see 19.2.7.4). All time indexes  
 8 from any time index pair that satisfies its corresponding  $\max AS_{xy}$  threshold is deemed to be trusted. The  
 9 time index that has the median time amongst all the trusted time indexes is selected as the output of the  
 10 MVTISA. If the number of trusted time indexes is even, the selected time index is the one with the smaller  
 11 index value.

12 **19.3.3.2.1 Process variables**

13 The variables used in the MVTISP are described in this subclause.

14 **19.3.3.2.1.1 `exclude_time_index[num_time_indexes]` (UInteger8)**

15 This variable `exclude_time_index[x]` is a vector, of size `num_time_indexes`, of Boolean values that  
 16 temporarily holds the index values of the trusted input ClockTarget interfaces as they are sorted into  
 17 ascending order.  
 18

19 **19.3.3.2.1.2 `hyst[num_time_indexes][num_time_indexes]`**

20 This variable is a two-dimensional array of fractional nanosecond values. The array has a size of  
 21 `num_time_indexes` in each dimension. This parameter holds the hysteresis added to  $\max AS[x][y]$  (see  
 22 19.3.3.2.1.3) for the times of the two ClockTarget interfaces with index numbers `x` and `y`.

23 The hysteresis enables the use of one time skew level to set the trust status and another time skew level to  
 24 clear the trust status.

25 **19.3.3.2.1.3 `maxAs[x][y]` (array of Uinteger32)**

26 The variable `maxAs[x][y]` is a two-dimensional array of values, where each value gives the maximum  
 27 magnitude of expected skew between times provided by the ClockTarget interface of index `x` and index `y`  
 28 when those times are not faulty. The variable  $\max AS[x][y]$  is given in units of  $2^{-16}$  ns. This value is used as  
 29 the criteria to determine the trustworthiness of the times being compared. See  $\max AS_{xy}$  in 19.2.7.4.

30 **19.3.3.2.1.4 `med_time_index` (UInteger8, NQ)**

31 This variable is the selected input ClockTarget interface index number. The range of values for the input  
 32 ClockTarget interfaces ranges from 1 to 255. The value of NQ represents a not-qualified time.

33 **19.3.3.2.1.5 `med_next_time_index` (UInteger8,NQ)**

34 This variable is the index number for the input ClockTarget interface that is deemed to be the trusted  
 35 partner for the selected input ClockTarget interface. The range of values for the input ClockTarget  
 36 interfaces ranges from 1 to 255. The value of NQ represents a not-qualified time.

1           **19.3.3.2.1.6 min\_value (ExtendedTimestamp)**

2           The variable min\_value is a temporary value used for sorting the trusted ClockTarget interfaces from their  
3           times, lowest to highest.

4           **19.3.3.2.1.7 num\_sorted (UInteger8)**

5           The variable num\_sorted holds a temporary count of the number of trusted time indexes that have been  
6           sorted in time ascending order.

7           **19.3.3.2.1.8 num\_time\_indexes (UInteger8)**

8           This variable num\_time\_indexes contains the number of input ClockTarget interfaces connected to the  
9           DTSA instance. This parameter has a minimum value of 1.

10          The value of num\_time\_indexes does not include the NQ time (see 19.3.2.2.3).

11          **19.3.3.2.1.9 ordered\_time\_index[num\_sorted] (vector of Uinteger8)**

12          The variable ordered\_time\_index[x] contains the Xth entry, starting from 1, of the trusted time indexes  
13          ordered from lowest to highest ToD value.

14          **19.3.3.2.1.10 prev\_trust\_status**

15          The variable prev\_trust\_status holds the last trust status of the DTSA. Valid values are NOT\_TRUSTED  
16          and NO\_TRUST, TIME\_TRUST, and FREQ\_TRUST.

17          **19.3.3.2.1.11 prev\_time\_index\_pair\_status[x][y]**

18          The variable prev\_time\_index\_pair\_status[x][y] holds the trust status between ClockTarget interface s and  
19          ClockTarget interface y. Valid values are NOT\_TRUSTED and TRUSTED.

20          **19.3.3.2.1.12 trust\_status (???)**

21          The variable trust\_status holds the type of trust the DTSA has currently advanced to. Valid values are  
22          NO\_TRUST, TIME\_TRUST, and FREQ\_TRUST.

23          **19.3.3.2.1.13 time\_index\_pair\_status[x][y] (???)**

24          The variable time\_index\_pair\_status[x][y] holds the trust status between ClockTarget Interfaces x and y.  
25          Valid values are UNTRUSTED and TRUSTED.

26          **19.3.3.2.1.14 time\_index\_status[x] (???)**

27          The variable time\_index\_status[x] holds the trust status of ClockTarget Interface x, Valid values are  
28          UNTRUSTED and TRUSTED.

29          **19.3.3.2.1.15 ToD[x] (vector of ExtendedTimestamp)**

30          The variable ToD[x] holds the latest timeReceiverTimeCallback result for input ClockTarget interface x.

1           **19.3.3.2.1.16 ToD\_Diff[x][y] (array of ExtendedTimestamp)**

2   The variable ToD\_Diff[x][y] gives the time skew between the two ClockTarget interfaces, x and y.

3           **19.3.3.2.1.17 x (UInteger8)**

4   The variable x is a local variable used for looping functions.

5           **19.3.3.2.1.18 y (UInteger8)**

6   The variable y is a local variable used for looping functions.

7

8           **19.3.3.2.2 Process pseudo-code**

9   Pseudo-code that represents the MVTISP is given below.

```

10 // #####
11 // Gather the current skews between the ToDs of all the time indexes.
12 // #####
13 For (x = 1; x <= num_time_indexes - 1, x++) {
14     For (y = x + 1, y <= num_time_indexes, y++) {
15         ToD_Diff[x][y] = |ToD[x] - ToD[y]|
16     }
17 }
18
19
20 // #####
21 // Clear status before starting a new round of time index comparisons.
22 // #####
23 trust_status = NO_TRUST
24 time_index_pair_status[x][y] = UNTRUSTED for all x and all y
25 time_index_status[x] = UNTRUSTED for all x
26 num_sorted = 1
27 exclude_time_index[x] = FALSE for all x
28
29
30 // #####
31 // Find all trusted time indexes, considering hysteresis.
32 // #####
33 For (x = 1, x <= num_time_indexes - 1, x++) {
34     For (y = x + 1, y <= num_time_indexes, y++) {
35         if ((ToD_Diff[x][y] <= maxAs[x][y] &&
36             prev_time_index_pair_status[x][y] == UNTRUSTED) ||
37             (ToD_Diff[x][y] <= (maxAs[x][y] + hyst[x][y]) &&
38             prev_time_index_pair_status[x][y] == TRUSTED)) &&
39             (isSynced_status[x] && gmPresent_status[x]) &&
40             (isSynced_status[y] && gmPresent_status[y]))
41         {
42             // trust found for the pair
43             trust_status = TIME_TRUST
44             time_index_pair_status[x][y] = TRUSTED
45             time_index_status[x] = TRUSTED
46             time_index_status[y] = TRUSTED
47             prev_time_index_pair_status[x][y] = TRUSTED
48         }
49     }
50 }

```

Individual Contribution: Fault-Tolerant Timing with Time Integrity

```

1           // trust not found for the pair
2           prev_time_index_pair_status[x][y] = UNTRUSTED
3       }
4   }
5 }
6
7
8 // #####
9 // If trust_status = TIME_TRUST, find time index with the mid-value ToD.
10 // #####
11 // Trusted times detected.
12 If {trust_status == TIME_TRUST)
13 {
14     // Update previous trust status.
15     prev_trust_status = TIME_TRUST
16
17     // Sort all trusted time indexes in order of their ToD, from smallest
18     // to largest using two loops.
19     // Outer loop iterates over all time indexes.
20     For (x = 1, x <= num_time_indexes, x++) {
21         min_value = 2^48 seconds // Start with ToD value that is larger
22                                 // than any possible gPTP ToD value.
23         // Inner loop finds and records the time index with the minimum ToD
24         // value and excludes it from further iterations of the outer loop.
25         For (y = 1, y <= num_time_indexes, y++) {
26             if (time_index_status[y] == TRUSTED &&
27                 exclude_time_index[y] == FALSE &&
28                 ToD[y] <= min_value)
29             {
30                 min_value = ToD[y] // record latest min ToD value found in the
31                                 // inner loop
32                 ordered_time_index[num_sorted] = y // record latest time index
33                                                     // with min ToD value
34             }
35         }
36         // Exclude latest time index with the min ToD value and add to sort index.
37         exclude_time_index[ordered_time_index[num_sorted]] = TRUE

11

### 12 **19.3.3.3 Default DTSA state machine**

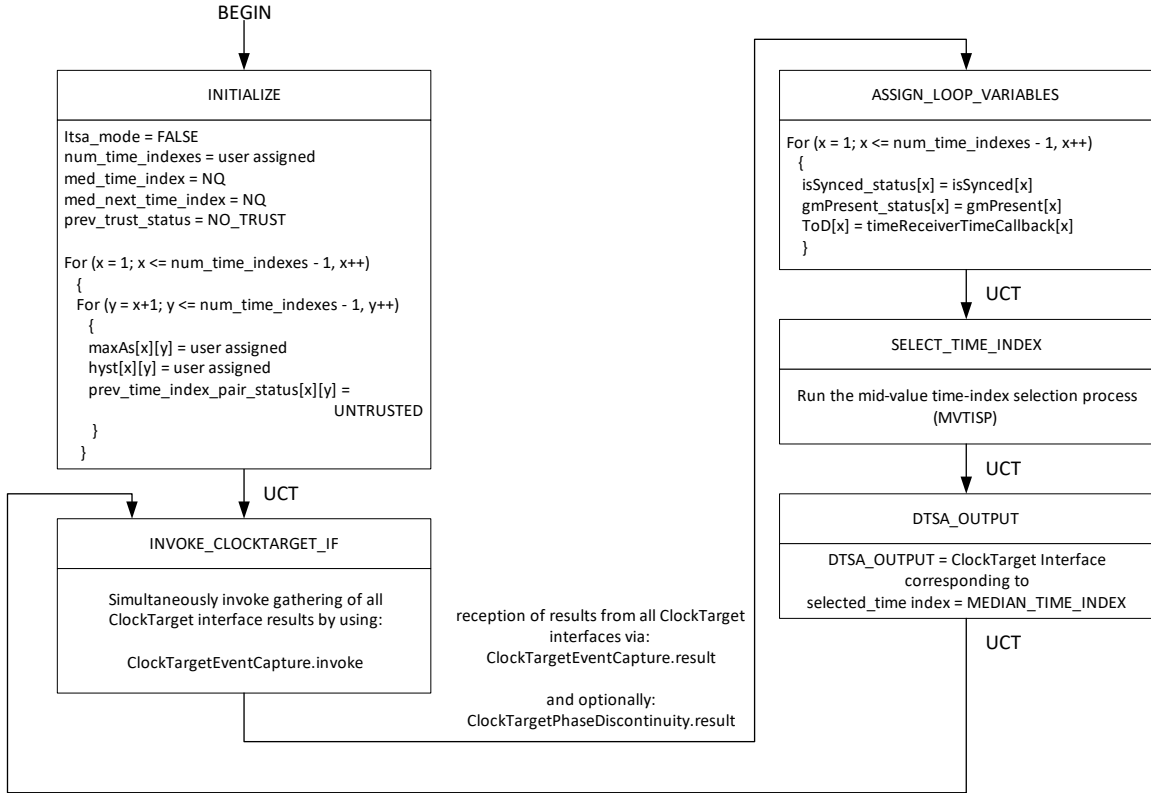

13 The default DTSA state machine uses the ClockTargetEventCapture interface.

#### 14 **19.3.3.3.1 State machine variables**

15 **Still to be added...**

#### 16 **19.3.3.3.2 State diagram**

17 The default DTSA state machine is shown in Figure 5. The default DTSA shall use the MVTISP of  
18 19.3.3.2 to find all the trusted input times and to select the index that corresponds to ClockTarget interface  
19 that holds the median ToD value from the trusted input times. The ClockTarget interface of the selected  
20 input dependent time shall be presented as the output of the default DTSA.

21

The INITIALIZE state of the default DTSA state machine sets up the starting values of variables. Once the starting values are configured, this state unconditionally transfers to the INVOKE\_CLOCKTARGET\_IF state.

The INVOKE\_CLOCKTARGET\_IF state of the default DTSA state machine simultaneously invokes all the ClockTarget interfaces connected to the DTSA instance to provide timing information. Once all the ClockTarget interfaces respond to the invocation with their timing information results, this state transitions to the ASSIGN\_LOOP\_VARIABLES state.

The ASSIGN\_LOOP\_VARIABLES state of the default DTSA state machine assigns three timing result parameters (isSynced, gmPresent, and timeReceiverTimeCallback see clause 9) from each of the ClockTarget interfaces to DTSA variables. Once this assignment is finished, this state unconditionally transfers to the SELECT\_TIME\_INDEX state.

The SELECT\_TIME\_INDEX state of the default DTSA state machine runs the MVTISP (see 19.3.3.2) to find the trusted times, if any, from the input ClockTarget interfaces, sort them in ascending ToD order, and identify the index number of the input ClockTarget interface with the median ToD value. If no trusted time is found, then the index number for the NQ time is identified. This index number is then passed to the DTSA\_OUTPUT state.

The DTSA\_OUTPUT state of the default DTSA state machine passes the ClockTarget interface identified by the MVTISP of the SELECT\_TIME\_INDEX state to the output of the DTSA's output.

1     **19.3.3.4 Default ITSA state machine**

2     The default ITSA state machine uses the ClockTargetEventCapture interface.

3             **19.3.3.4.1 State machine variables**

4     Still to be added...

5             **19.3.3.4.1.1 itsaRateRatio[num\_input\_times] (vector of Float64)**

6     The variable itsaRateRatio[x] is equal to the ratio of the clock frequency of the time arriving on input  
7     ClockTarget interface x to the frequency of the FTTM's local clock, OSC\_CLK.

8

9             **19.3.3.4.2 State diagram**

10    The default ITSA state machine is shown in Figure 6 and Figure 7. The default ITSA shall use the MVTISP  
11    of 19.3.3.2 to find all the trusted input times and to select the index that corresponds to ClockTarget  
12    interface that holds the median ToD value from the trusted input times or the index that corresponds to the  
13    NQ time if no trusted time is available. The ClockTarget interface of the selected time shall be presented as  
14    the output of the default ITSA and, hence, as the output of the FTTM.

Individual Contribution: Fault-Tolerant Timing with Time Integrity

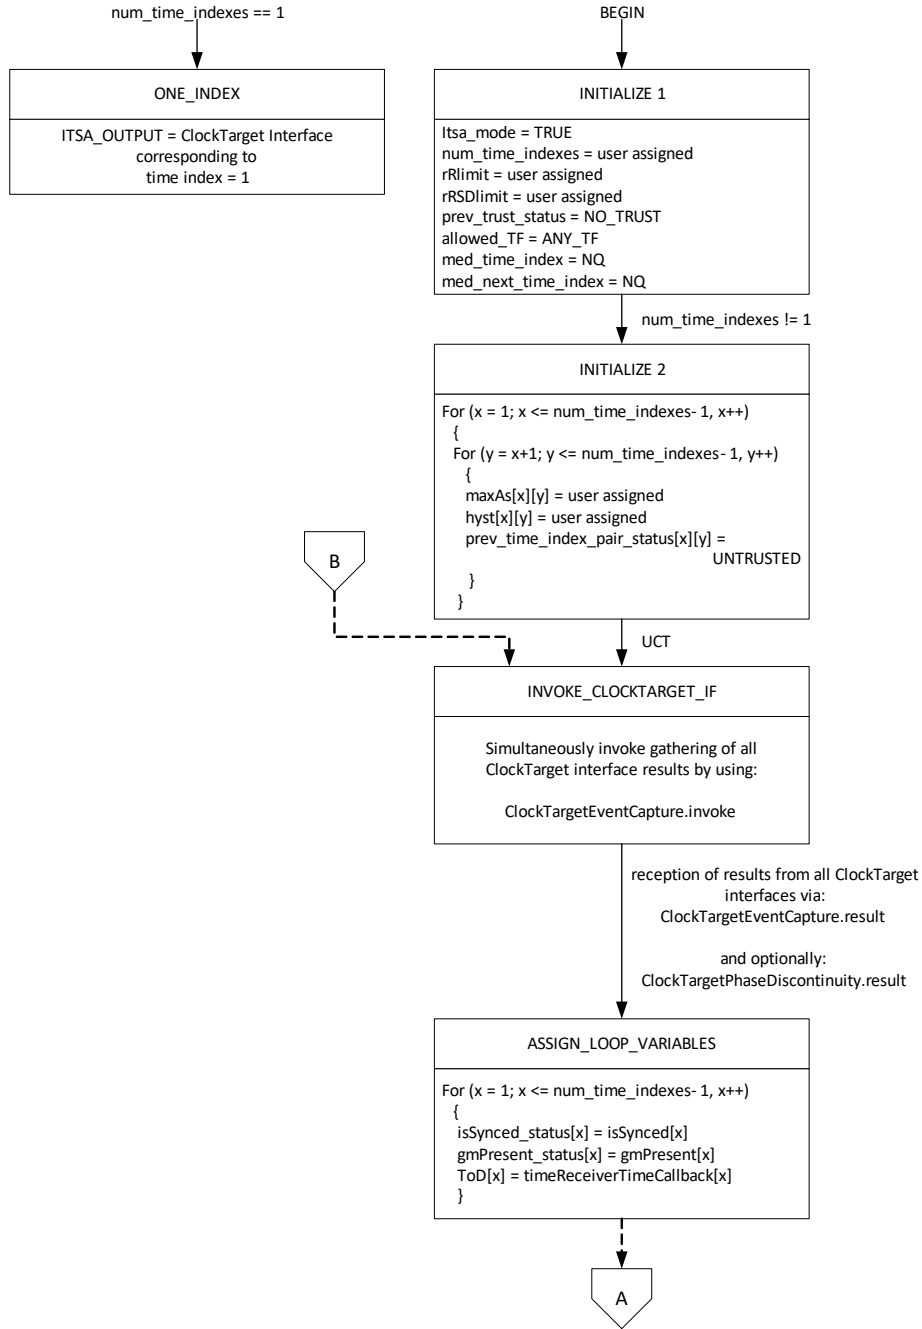

Figure 6—ITSA state machine, part 1

1  
2  
3

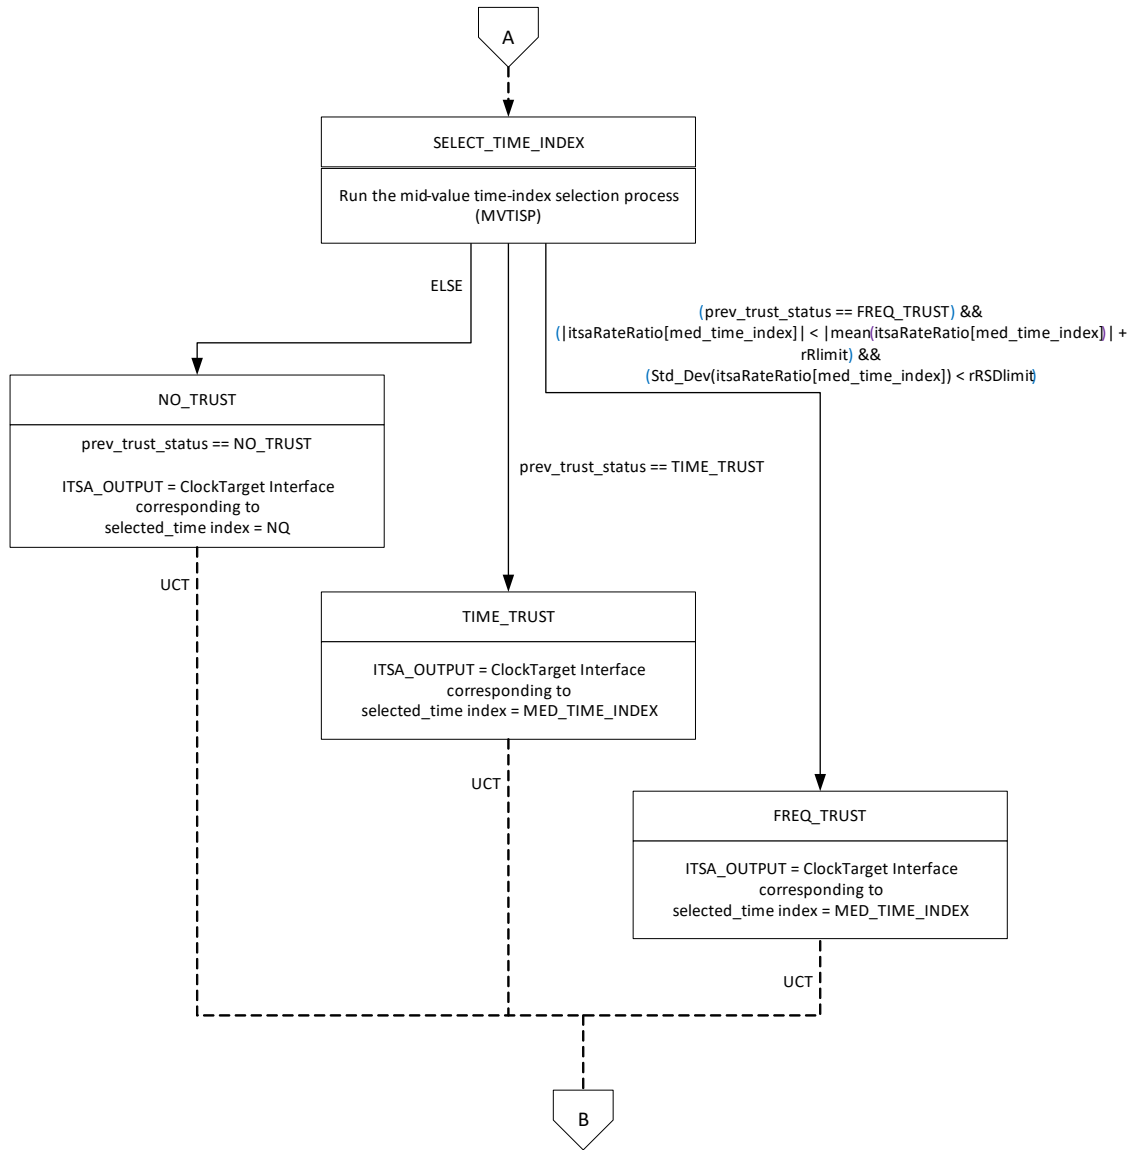

Figure 7—ITSA state machine, part 2

1  
2  
3

4 The INITIALIZE 1 state of the default ITSA state machine sets up the starting values of some variables.  
 5 Once these starting values are configured, this state unconditionally transfers to the INITIALIZE 2 state  
 6 except for the case in which the assigned value of num\_time\_indexes is equal to one, in which the state  
 7 instead transfers to the ONE\_INDEX state.

8 The ONE\_INDEX state of the default ITSA state machine is used when there is only one input ClockTarget  
 9 interface connected to the ITSA. This corresponds to the regular availability and no integrity operational  
 10 scenario described in 19.3. The state machine can only exit this state via the BEGIN condition.

11 The INITIALIZE 2 state of the default ITSA state machine sets up the starting values of variables that only  
 12 make sense when the assigned value of num\_time\_indexes is greater than one. Once these starting values  
 13 are configured, this state unconditionally transfers to the INVOKE\_CLOCKTARGET\_IF state.

1 The INVOKE\_CLOCKTARGET\_IF state of the default ITSA state machine simultaneously invokes all the  
2 ClockTarget interfaces connected to the ITSA instance to provide timing information. Once all the  
3 ClockTarget interfaces respond to the invocation with their timing information results, this state transitions  
4 to the ASSIGN\_LOOP\_VARIABLES state.

5 The ASSIGN\_LOOP\_VARIABLES state of the default ITSA state machine assigns three timing result  
6 parameters (isSynced, gmPresent, and timeReceiverTimeCallback see clause 9) from each of the  
7 ClockTarget interfaces to ITSA variables. Once this assignment is finished, this state unconditionally  
8 transfers to the SELECT\_TIME\_INDEX state.

9 The SELECT\_TIME\_INDEX state of the default ITSA state machine runs the MVTISP (see 19.3.3.2) to  
10 find the trusted times, if any, from the input ClockTarget interfaces. If trusted times are found, it sorts them  
11 in ascending ToD order and identifies the index number of the input ClockTarget interface that has the  
12 median ToD value.

13 — If the MVTISP returns a prev\_trust\_status = TIME\_TRUST, this means that it has found a trusted  
14 time and selected a corresponding ClockTarget interface. The index of the selected ClockTarget  
15 interface is provided as the output of the SELECT\_TIME\_INDEX state and the state machine  
16 transitions to the TIME\_TRUST state.

17 — If the MVTISP returns a prev\_trust\_status = FREQ\_TRUST, this means that it has trust time but is  
18 trying to keep operating with the last selected ClockTarget interface, which still has isSynced and  
19 gmPresent asserted as TRUE. This last selected ClockTarget interface is presented as the output of  
20 the SELECT\_TIME\_INDEX state. If this ClockTarget interface is still providing a time that is  
21 incrementing consistently with respect to the FTTM's local clock (OSC\_CLK), as determined by  
22 the itsaRateRatio[x] measurement for the ClockTarget interface, then the state machine transitions  
23 to the FREQ\_TRUST state.

24 — If neither of the above cases is true, then the ITSA has no trust in any of its input times. The state  
25 machine transitions to the NO\_TRUST state.

26 The NO\_TRUST state of the default ITSA state machine passes the NQ index to the output of the ITSA's  
27 output and, hence, the FTTM's output. This indicates that no trusted time is being passed from the FTTM.  
28 The state machine unconditionally transitions back to the INVOKE\_CLOCKTARGET\_IF state to start  
29 another round of integrity checking.

30 The TIME\_TRUST and the FREQ\_TRUST states of the default ITSA state machine both pass the  
31 ClockTarget interface identified by the MVTISP of the SELECT\_TIME\_INDEX state to the output of the  
32 ITSA's output and, hence, the FTTM's output. This indicates that a trusted time is being passed from the  
33 FTTM. The state machine unconditionally transitions back to the INVOKE\_CLOCKTARGET\_IF state to  
34 start another round of integrity checking.

### 3 **J.1 Introduction**

4 This Annex provides examples for time synchronization with fault tolerance and time integrity.

5 Time-sensitive applications that require fault tolerance are expected to tolerate multiple (typically 2)  
6 simultaneous arbitrary faults in end stations, Bridges, links, and GMs while maintaining availability and  
7 integrity of time synchronization.

8 Fault tolerance, or availability, and integrity address the reliable and accurate transmission of time values  
9 and the associated sync and follow-up messages in the presence of arbitrary faults in the network (link,  
10 Bridge, end station, and GM). Thus, under fault conditions, a correctly operating end station is expected to  
11 maintain a target maximum time error relative to the correctly operating GM. If unable to remain within the  
12 maximum time error, the correctly operating end station will detect an erroneous time synchronization  
13 state. To support this, it is expected that multiple clock domains are configured and managed in the  
14 network.

### 15 **J.2 Clock domain management**

16 As described in 19.2, clock domains can be considered dependent or independent. Independent clock  
17 domains, where ClockSources are independent, are expected to present problems to the integrator because,  
18 at the time of writing, commercially available devices cannot be relied upon to support multiple  
19 independent gPTP Instances at a single port. This makes it problematic to bridge synchronized traffic  
20 between domains. In Figure J-1, two clock domains D1 and D2 are shown overlapping at Bridges B2 and  
21 B3 with streams S1 and S2 sharing a common output port, P4, on B2. If the two clock domains are  
22 synchronized, Bridges B2 and B3 will synchronize to the common domain time and will be able to forward  
23 both streams to the downstream end stations. However, if the two clock domains are not synchronized, then  
24 a conflict can occur on the shared output port of B2 such that it must either maintain two PTP Instances on  
25 the shared output port and widen the output windows to accommodate a potential conflict or must forward  
26 one of the streams in an unsynchronized manner.

27 It is not possible for a device to support multiple unsynchronized gate schedules on a single output port,  
28 and aerospace networks using multiple PTP domains should therefore ensure that the clock domains are  
29 either dependent on a common ClockSource or are synchronized to each other by some other means (see  
30 19.2.1).

31 Management of multiple PTP instances using a fault-tolerant timing module (FTTM) is discussed in 19.3.

### 35 **J.3 Time agreement generation examples**

36

1 PPS-based implementations.

2 TTE-based implementations.

3

#### 4 **J.4 Balancing availability and integrity**

5 A common time source is used for all GMs.

6 Only 2 domains are used, instead of 3 or more.

7 An insufficient number of independent paths are available in the network for all PTP domains.

8

#### 9 **J.5 FTTM operation in example network topologies**

10 **A.1.1 N x point-to-point network (one for each gPTP domain)**

11

12 **A.1.2 Dual-homed network**

13

14 **A.1.3 Multi-homed network**

15

16 **A.1.4 Dual-star network**

17

18 **A.1.5 Bidirectional ring network**

19

20 **A.1.6 Mesh network**
