Re:	Call for Evaluations and Improvements, IEEE 802.16.1, Session #7.	
Abstract	The following ECC proposal is submitted as further improvement to the ECC coding scheme of the PHY proposal 802.16.1pc-00/19 . The proposal is consistent with previous contribution 802.16.1pc-00/18 , which applies to two main current PHY proposals.	
Purpose	To provide a description of a proposed ECC for Mode B of proposal IEEE 802.16.1pc-00/19 .	
Notice	This document has been prepared to assist IEEE 802.16. It is offered as a basis for discussion and is not binding on the contributing individual(s) or organization(s). The material in this document is subject to change in form and content after further study. The contributor(s) reserve(s) the right to add, amend or withdraw material contained herein.	
Release	The contributor grants a free, irrevocable license to the IEEE to incorporate text contained in this contribution, and any modifications thereof, in the creation of an IEEE Standards publication; to copyright in the IEEE's name any IEEE Standards publication even though it may include portions of this contribution; and at the IEEE's sole discretion to permit others to reproduce in whole or in part the resulting IEEE Standards publication. The contributor also acknowledges and accepts that this contribution may be made public by IEEE 802.16.	
IEEE Patent Policy	<p>The contributor is familiar with the IEEE 802.16 Patent Policy and Procedures (Version 1.0) <http://ieee802.org/16/ipr/patents/policy.html>, including the statement "IEEE standards may include the known use of patent(s), including patent applications, if there is technical justification in the opinion of the standards-developing committee and provided the IEEE receives assurance from the patent holder that it will license applicants under reasonable terms and conditions for the purpose of implementing the standard."</p> <p>Early disclosure to the Working Group of patent information that might be relevant to the standard is essential to reduce the possibility for delays in the development process and increase the likelihood that the draft publication will be approved for publication. Please notify the Chair <mailto:r.b.marks@ieee.org> as early as possible, in written or electronic form, of any patents (granted or under application) that may cover technology that is under consideration by or has been approved by IEEE 802.16. The Chair will disclose this notification via the IEEE 802.16 web site <http://ieee802.org/16/ipr/patents/letters>.</p>	

An Amendment to Mode B of IEEE 802.16.1pc-00/19

Moshe Ran

mran@telesciCOM.com

1.0 Introduction

This document specifically addresses an amendment to the adaptive modulation mode proposed in **802.16.1pc-00/19** denoted there MODE B. In compliance with our previous proposal **802.16.1pc-00/18** [1] we propose to replace the traditional Reed-Solomon (RS) codes by binary block product codes and use Soft-in\Soft-out (SISO) iterative decoders (i.e. "Block Turbo Codes", BTC). Compatibility with baseline downstream modes of the 802.16.1pc-00/19 [2] includes: Transmission Convergence (TC) layer, scrambling for energy dispersal, preamble prepend and baseband pulse shaping. The bit mapping to Gray coded QPSK, 16QAM and optionally 64QAM constellation are compatible with 802.16.1pc-00/20 [3].

1.1 Background

Iterative Soft-in\Soft-out (SISO) decoders ("Turbo Codes") and especially BTC are subjected to further consideration as ECC scheme for the PHY layer of the IEEE802.16.1.

Compared to traditional Error Control Coding (ECC) schemes such as Reed-Solomon (RS) codes, convolutional codes, concatenation of both (i.e. Reed-Solomon Viterbi, RSV), or concatenation of RS with other binary inner block codes (i.e., [3]) the BTC techniques are more appealing in BWA applications. ECC schemes based on Turbo Decoding outperform the legacy ECC in terms of coding gain. Furthermore, SISO iterative decoders have inherent ingredient that allow the highest performance when compared to other decoding strategies. Technological limitation of the two stage concatenated coding scheme, including the recent one [3] is far from optimal performance.

We propose a binary product code based on shortened Hamming codes for the downstream PHY layer, which match the framing format requirements of MODE B in proposal [2].

1.2 Convention and notations

(n, k, d) is a linear block code of length n dimension k and minimum Hamming distance d . The ratio k/n is the code rate. In many cases we shall drop the last parameter and we shall refer to (n, k) block code.

$(n_1, k_1, d_1) \times (n_2, k_2, d_2)$ is a general representation of a block code with length $n=n_1n_2$ dimension $k=k_1k_2$ and minimum distance $d=d_1d_2$. The code constructed in this way is called a "product code" (or 2-D array code), and (n_i, k_i) for $i=1,2$ are called the components codes. The codewords of the product code can be described by an n_1 times n_2 rectangular array, where the columns are a codewords of code (n_1, k_1) and the rows are codewords of (n_2, k_2) .

The general product code based on shortened binary Hamming codes as component codes is given by $(2^m - S_1, 2^m - m - 1 - S_1, 4) \times (2^m - S_2, 2^m - m - 1 - S_2, 4)$.

This code is called a Hamming Product Code, **HPC(m, S1,S2)**.

The case where $S_1=S_2$ leads to a highly symmetric case since the columns encoder is identical to the rows encoder. Symmetric HPC codes are highly desired since they result in implementation reduction.

Examples:

1. An MPEG package contains 188 bytes of 8 bits each. Thus, a product code which contains exactly these $188 \times 8 = 1504$ bits is realized with the following parameters:

$$m = 6, S1 = 25, S2 = 10.$$

This implies (39, 32) and (54, 47) shortened Hamming components codes which constitute the binary product code $(39 \times 54, 32 \times 47, 4 \times 4) = (2106, 1504, 16)$ with code rate 0.714.

2. Symmetric HPC for the MPEG frame (see [1]) can have the following parameters

$$\text{HPC}(m=6, S1=S2=18) = (46, 39) \times (46, 39) = (2116, 1521, 16)$$

3. Symmetric HPC for 128 Bytes frame

$$\text{HPC}(m=6, S1=S2=25) = (39, 32) \times (39, 32) = (1521, 1024, 16)$$

The shortened Hamming code $(64-S, 57-S)$ with shortening parameter S shall be implemented by appending S bits, all set to zero, before the information bits at the input of $(64, 57)$ extended Hamming encoder. This encoder shall be implemented by appending a parity check column the generator matrix of the Hamming code $(63, 57)$ generated by the primitive polynomial of degree 6:

$$g(x) = X^6 + X^1 + 1$$

2.0 Mode B Downstream Physical Media Dependent (PMD) sublayer

The encoding and decoding functions for the MODE B downstream physical layer is based on burst type architecture for the PMD sublayer. As a result, a sequence of 1 ms frames is transmitted. The underlying frame structure assumes integer number of physical slots (PS) each consists of 4 modulation symbols, where 4, 16, 64-QAM modulation are allowed. Thus PS for QPSK consists of 1 byte while for 16QAM and 64QAM the PS consists of 2, 3 bytes, respectively. The proposed ECC in ref [2] for MODE B is RS(192, 164).

The RS(192, 164) can be replaced by HPC as follows:

Option 1: $\text{HPC}(m=6, S1=25, S2=18) = (39, 32) \times (48, 41) = (1872, 1312, 16)$

Option 2: Symmetric HPC based on $\text{HPC}(m=6, S1=S2=21) = (43, 36) \times (43, 36) = (1849, 1296, 16)$

3.0 Summary and Recommendations

SISO iterative decoders based on Hamming Product codes (HPC) are suggested as an amendment to the PHY proposals of [2]. Since the code presented have almost the same code rate as given for the codes presented in [1] the resulted error performance versus normalized signal-to-noise ratio are almost the same.
