1 Introduction

This contribution provides a modification to the Uplink channel sounding methodology in Section 8.4.6.2.7 of IEEE 802.16e to include the optional direct transmission of DL channel coefficients [1][2] in addition to the sounding waveform. The modification extends the UL channel sounding signaling to enable closed-loop transmission in FDD systems and TDD systems in which BS array transceiver calibration is not implemented. The modification consists of an additional bit in the UL_Sounding_Command_IE() for the purpose of indicating whether or not channel coefficients are to be transmitted along with the sounding waveform in the sounding zone. When this functionality for the direct transmission of channel coefficients is used, the sounding waveform specified by the Sounding Command enables the BS to estimate the UL channel, which the BS then uses to estimate the DL channel coefficients being sent by the MSS in the subsequent symbol interval(s). These estimated DL channel coefficients can then be used by the BS to perform closed-loop transmit precoding.

[Add a new section 8.4.6.2.7.3 “Direct transmission of channel coefficients”. Add the following text.]

Section 8.4.6.2.7.3 Direct transmission of DL channel coefficients

If the “Include additional feedback” field is set to 01, then the UL Sounding Command IE() enables the MSS to perform the direct transmission of DL channel coefficients to the BS along with the UL sounding waveform. This functionality provides downlink channel state information to the BS in both FDD systems and TDD systems in which BS array transceiver calibration is not implemented. With this functionality enabled, DL channel coefficients are encoded as described below and are transmitted in one or more sounding zone symbols that immediately following each symbol being used to transmit UL sounding waveforms. In this case, the UL sounding waveform is used by the BS to estimate the UL channel so that the DL channel coefficients transmitted by the MSSs can be estimated by the BS. The channel coefficients can then be used to enable closed-loop transmission on the downlink.

There are two cases depending on the value of the separability type field. First, if separability type is 0 (cyclic shift separability in the sounding waveform), then a single additional symbol follows each sounding symbol being allocated with the UL Sounding command IE(). In that additional symbol, an MSS antenna that transmits sounding in the sounding symbol will transmit an encoded channel coefficient waveform that occupies the same sounding bands allocated for the sounding waveform. The encoded waveform for the u^{th} MSS (where u is the cyclic shift index in the UL Sounding Command) is defined for two cases: The first case is for where the MSS has a single transmit antenna, but multiple receive antennas, and is told with the sounding

command IE to sound all antennas (multi-antenna flag set to 1). In this case, the single transmit antenna transmits the sounding waveform appropriate for the single transmit antenna on the sounding symbol and transmits the following encoded waveform in the next symbol interval:

$$Z_u(k) = \beta_u \sum_{\ell=1}^{M_b} \sum_{m=1}^{M_{m,u}} \hat{H}_{u,m,\ell}(k) s_{p(u)}(k) \exp\{-j2\pi k(m-1 + (\ell-1)M_{m,u})/\alpha_u\}$$

where $\hat{H}_{u,m,\ell}(k)$ is the estimated DL channel coefficient between the ℓ^{th} BS transmit antenna and the m^{th} receive antenna of the u^{th} MSS for subcarrier k ; β_u is a scaling to make the average transmit power of the feedback waveform (averaged across all frequency) of $Z_u(k)$ be one; $s_{p(u)}(k)$ is the sounding sequence of Section 8.4.6.2.7.1; $M_{m,u}$ is the number of receive antennas on the u^{th} MSS, α_u is $M_{m,u}M_b$; and M_b is the number of BS transmit antennas, and $p(u)$ in $s_{p(u)}(k)$ is equal to $u-j$, where u is formed from the UL_IDcell and frame number as described in 8.4.6.2.7.1 and j is the CID loop index.

The second case for a separability type of 0 is for when the MSS has a number of transmit antennas equal to the number of receive antennas. In this case, if the multi-antenna flag is false, then the first antenna of the MSS shall transmit the waveform of the preceding equation. If the multi-antenna flag is true, then the encoded waveform to be transmitted by the MSS antenna assigned to cyclic shift index of u in the UL Sounding Command is

$$Z_u(k) = \beta_u \sum_{\ell=1}^{M_b} \hat{H}_{u,\ell}(k) s_{p(u)}(k) \exp\{-j2\pi k(\ell-1)/\alpha_u\}$$

where $\hat{H}_{u,\ell}(k)$ is the estimated DL channel coefficient between the ℓ^{th} BS transmit antenna and the MSS antenna assigned to the cyclic shift index of u in the UL Sounding Command for subcarrier k ; β_u is a scaling to make the average transmit power of the feedback waveform (averaged across all frequency) of $Z_u(k)$ be one; $s_{p(u)}(k)$ is the sounding sequence of Section 8.4.6.2.7.1; α_u is M_b ; and M_b is the number of BS transmit antennas, and $p(u)$ in $s_{p(u)}(k)$ is equal to $u-j$, where u is formed from the UL_IDcell and frame number as described in 8.4.6.2.7.1 and j is the CID loop index.

When separability type is 1 in the UL Sounding Command (decimation separability in the sounding waveform), then the “use same symbol for additional feedback” bit specifies whether the additional feedback is sent in the symbol(s) following the allocated sounding symbol, or in the same symbol as the allocated sounding symbol. These two cases are described as follows.

If separability type is 1 and “use same symbol for additional feedback bit” is true, then a number of additional sequential decimation offset indices equal to the number of MSS receive antennas is used for the encoded feedback waveform (e.g., if a decimation offset of 1 is used for the uplink sounding, then decimation offsets 2 and 3 are the additional decimation offsets used for the additional feedback for a two receive antenna MSS). On the i^{th} additional decimation offset, the first MSS transmit antenna transmits the following waveform:

$$Z_1(k) = \beta_u \sum_{\ell=1}^{M_b} \hat{H}_{i,\ell}(k) s_{p(u)}(k) \exp\{-j2\pi k(\ell-1)/\alpha_u\}$$

where $\hat{H}_{i,\ell}(k)$ is the estimated DL channel coefficient between the ℓ^{th} BS transmit antenna and the i^{th} receive MSS antenna, β_u is a scaling to make the average transmit power of the feedback waveform (averaged across all frequency) of $Z_u(k)$ be one; $s_{p(u)}(k)$ is the sounding sequence of Section 8.4.6.2.7.1; α_u is M_b ; and M_b is the

number of BS transmit antennas, and $p(u)$ in $s_{p(u)}(k)$ is equal to $u-j$, where u is formed from the UL_IDcell and frame number as described in 8.4.6.2.7.1 and j is the CID loop index. For this type of feedback, the multi-antenna flag in the sounding command should be set to zero so that only the first antenna of the MSS transmits the required sounding waveform and only the first antenna of the MSS transmits the feedback waveform.

If separability type is 1 and “use same symbol for additional feedback bit” is false, then every allocated sounding symbol is followed by a number of additional symbols equal to the number of BS antennas. When an MSS has a number of receive antennas equal to its number of transmit antennas, then an MSS antenna that transmits on subcarrier k of the sounding symbol shall transmit the DL channel coefficient for the i^{th} base antenna to the corresponding MSS receive antenna for the k^{th} subcarrier on subcarrier k of the i^{th} additional symbol following the allocated sounding symbol. In equation form, the MSS that transmits a sounding signal on subcarrier k of the sounding symbol shall transmit $\hat{H}_\ell(k)$ on the ℓ^{th} symbol following the sounding symbol, where $\hat{H}_\ell(k)$ is the DL channel coefficient from the ℓ^{th} BS antenna to the corresponding MSS receive antenna. When the MSS has a single transmit antenna and multiple receive antennas, then the first MSS transmit antenna transmits any sounding and feedback requested in the sounding command.

[Add a new section 8.4.6.2.7.4 “Feedback of Received Pilot Coefficients”. Add the following text.]

Section 8.4.6.2.7.4 Feedback of Received Pilot Coefficients

If the “Include additional feedback” field is set to 10, the UL Sounding Command IE() enables the MSS to transmit additional feedback based on the downlink received pilot signal values in the frequency domain. In this case, a single additional symbol is used to transmit a subset of the received pilot values back to the BS. For the case of a MIMO midamble being used as the source of the received pilots, the midamble received by each SS antenna is decimated in a blockwise fashion, block interlaced to reconstruct the feedback symbol, and sent back on the additional symbol interval. (Blockwise decimation by p with a block size of q means to retain one block of q consecutive samples out of every pq consecutive samples, and a block decimation offset of r means that the r^{th} block of length q is the first one to be retained.) For the received MIMO midamble, the blockwise decimation factor p shall be set equal to the number of SS receive antennas, the block size q shall be set equal to the number of BS antennas, and the blockwise decimation offset value depends on the receive antenna number of the SS. The blockwise decimation offset for SS receive antenna m ($m = 1, 2, \dots$) is $m-1$. Before being transmitted, the power of this additional symbol shall be normalized to the same level as the sounding symbol which precedes it.

3 Appendix: Simulation Results

Example simulations results are presented for the following closed loop techniques, for the case of broadband transmission.

- CQI channel based techniques: Antenna grouping, antenna selection, and codebook techniques. Both antenna grouping and antenna selection are assumed to need only 2 bits to select the antenna combination (although in the actual system the number of required bits may be 3 since there is no 2 bit CQI definition – rather, a 3 bit CQI is being proposed by others). The codebook-based approach is assumed to use a 6 bit codebook.
- Sounding-based techniques: uplink sounding (as in 802.16e), direct channel feedback (proposed enhancement for FDD systems, this contribution)
- Speeds: Results are shown for both quasi-static channels (no velocity, but independent fading draws for different simulation trials) to identify the gains for slowly fading channels, and for high velocity. The high velocity case is for 50 kph at 2.6 GHz, and we assume a 10 ms delay between the time where the downlink channel is measured and when the CL-MIMO transmission is made based on that DL measurement (e.g., a 10 ms feedback delay).
- System: 2048 FFT in 20 MHz, turbo coding over all subcarriers. This represents a broadband scenario when an SS is allocated most or all of the channel bandwidth in order to get the maximum data rate.
- Channel Model: Cost 259-based spatial channel model, 2 us delay spread, 15 degree angular spread. Transmit antenna spacing at the BS is 1 wavelength or 5 wavelengths. For all cases, the uplink SNR is fixed at 0 dB.
- Channel Frequency Tracking Strategy: Track the frequency selective channel as much as possible with each technique, for the same total feedback overhead. Techniques with compact feedback get better frequency tracking than others (e.g., antenna selection with 2 bits gets 3x better frequency tracking than the 6-bit codebook). The normalized uplink feedback overhead set to be equivalent to a single OFDM symbol per broadband SS. For antenna selection and grouping, that means a new grouping (2 bits) is selected every 24 subcarriers. For direct channel coefficient feedback, a decimation of 2 is used, and for the 6 bit codebook-based technique a new selection is made from the codebook every 72 subcarriers.
- Results are shown in the next figures. For each case, different modulation and coding rates are simulated (from $R=1/4$ QPSK up to $R=3/4$ 64-QAM), and a hull curve is created by selecting the best modulation/coding scheme for each SNR. The vertical axis represents the bits/subcarrier obtained after taking the frame error rate into account (e.g., $R=1/2$ QPSK with no errors would provide 1 bit/subcarrier).

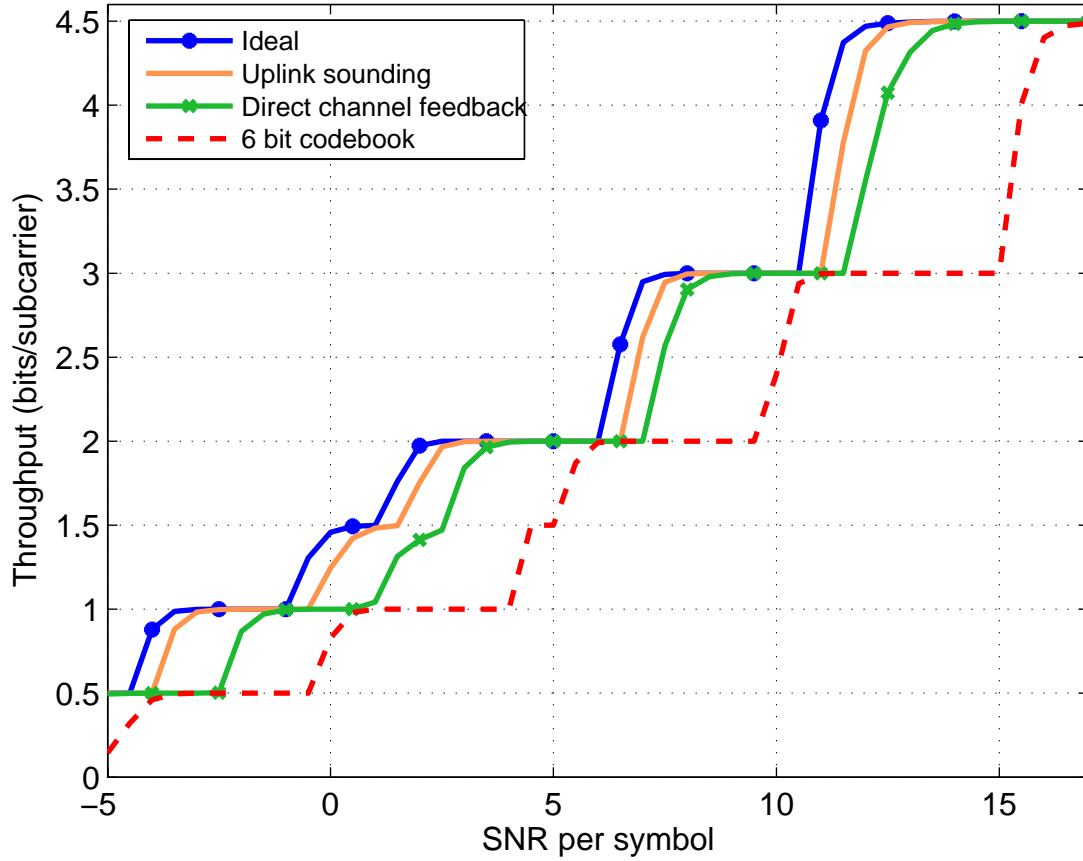

Figure 1. Simulation results for 4 Tx antennas at the BS (5λ spacing) and one receive antenna at the SS. Faded quasi-static (near-zero velocity) case. Results are shown for ideal instantaneous per-subcarrier channel knowledge, uplink sounding, direct channel feedback (this contribution), and the 6 bit codebook.

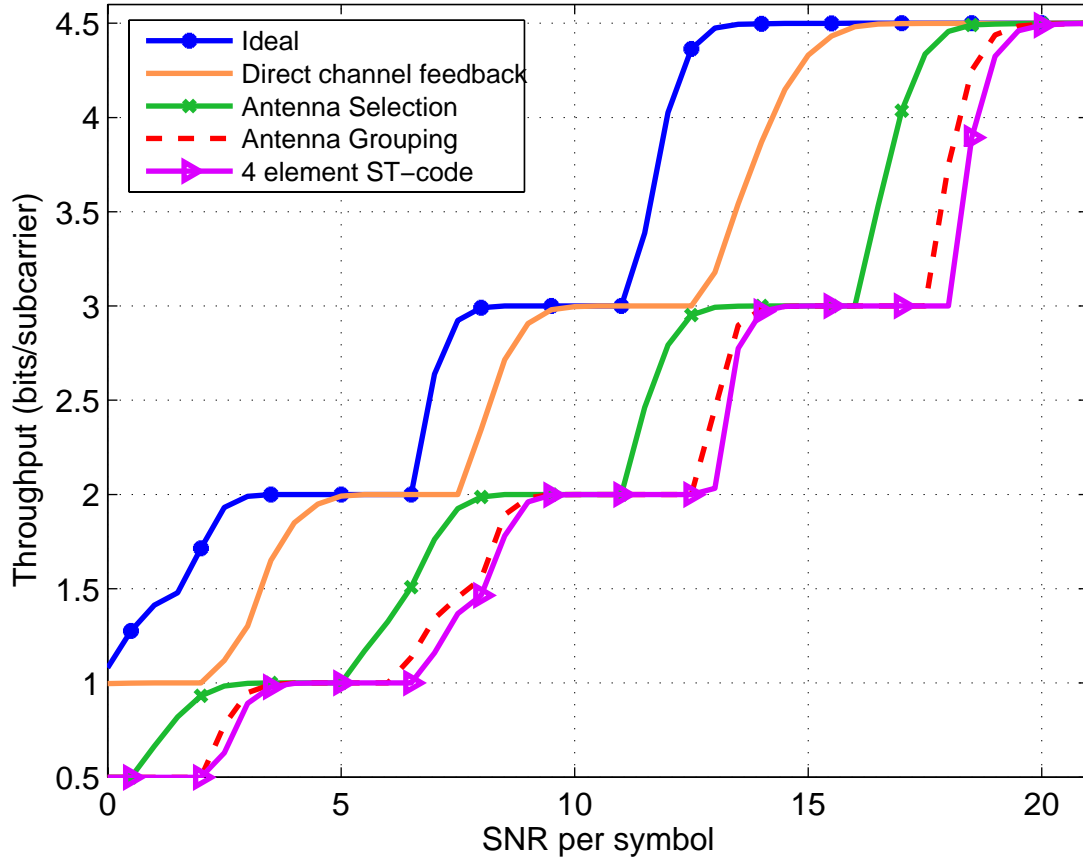

Figure 2. Simulation results for 4 Tx antennas at the BS (1λ spacing) and one receive antenna at the SS. Faded quasi-static (near-zero velocity) case. Results are shown for ideal instantaneous per-subcarrier channel knowledge, direct channel feedback (this contribution), antenna selection, antenna grouping, and open-loop space-time coding.

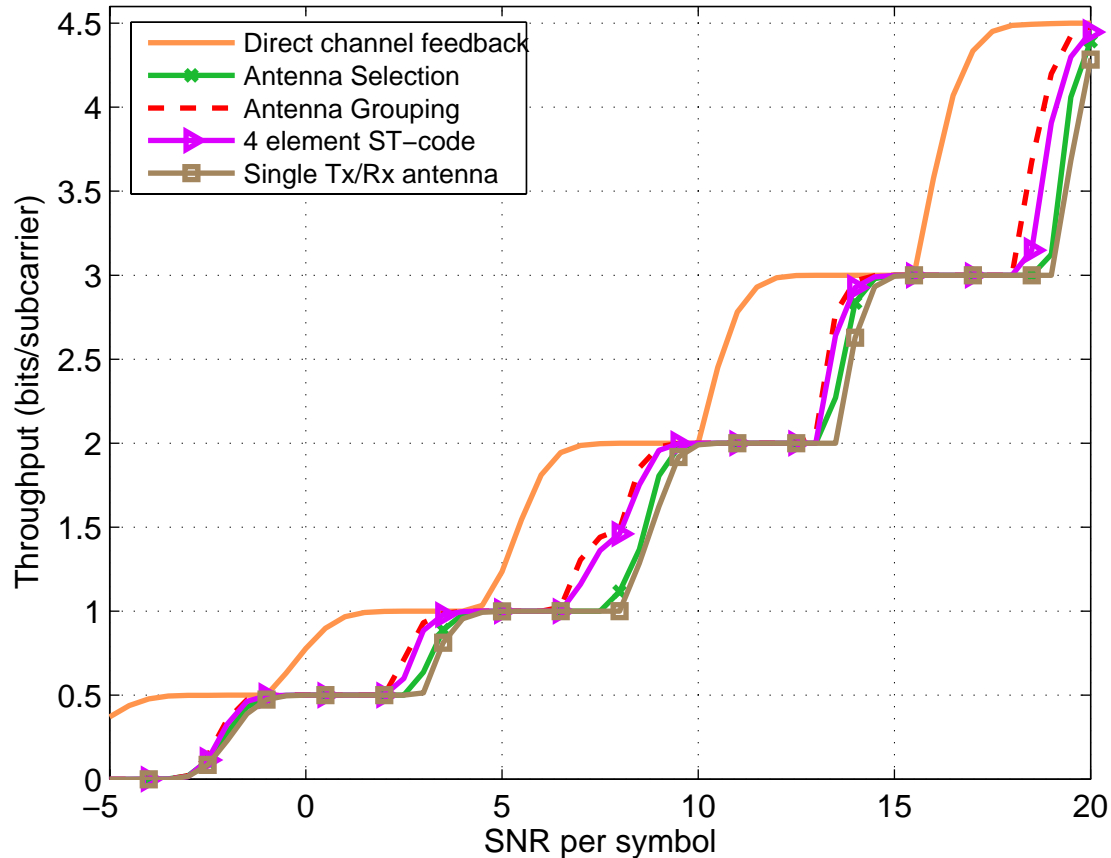

Figure 3. High velocity case: 50 kph at 2.6 GHz with a 10 ms of feedback delay. 4 Tx antennas at the BS (1λ spacing) and one receive antenna at the SS. Results are shown for antenna selection, antenna grouping, open-loop space-time coding, and direct channel feedback (this contribution). In this example, the direct channel feedback is averaged and the averaged information is used to set the transmit weights, thus providing a performance gain even in the high velocity case due to the finite angular spread of the channel.
