# Overview

---

- **Simulation of Signal Detector**
- **Simulations of Startup State Machine**
- **Probability of restart**
- **Fast Link Pulses (FLP) and signal detect**
- **Conclusions**

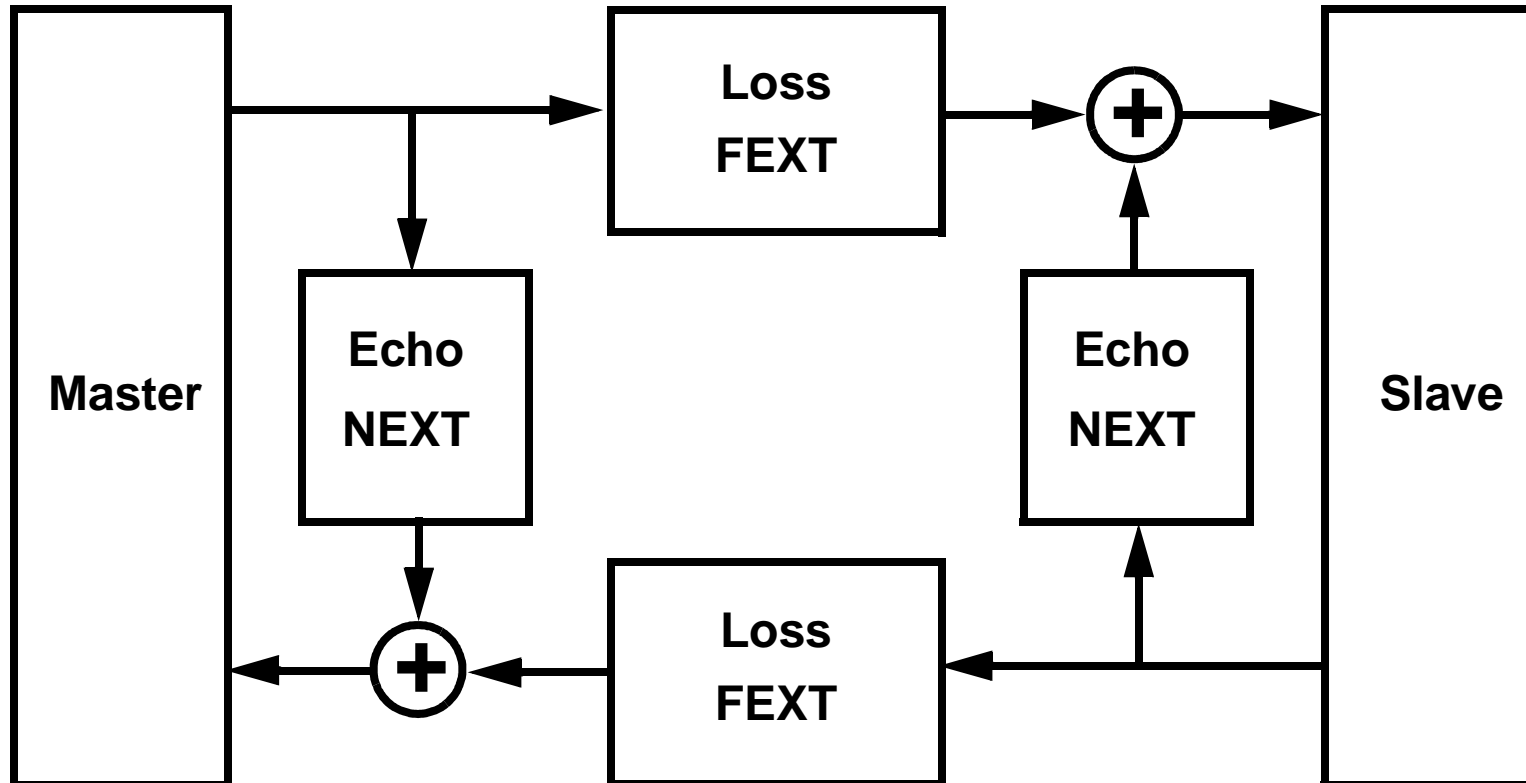

# Signal Detection in an Echo Cancellation Environment

---

# Simulation Model

---

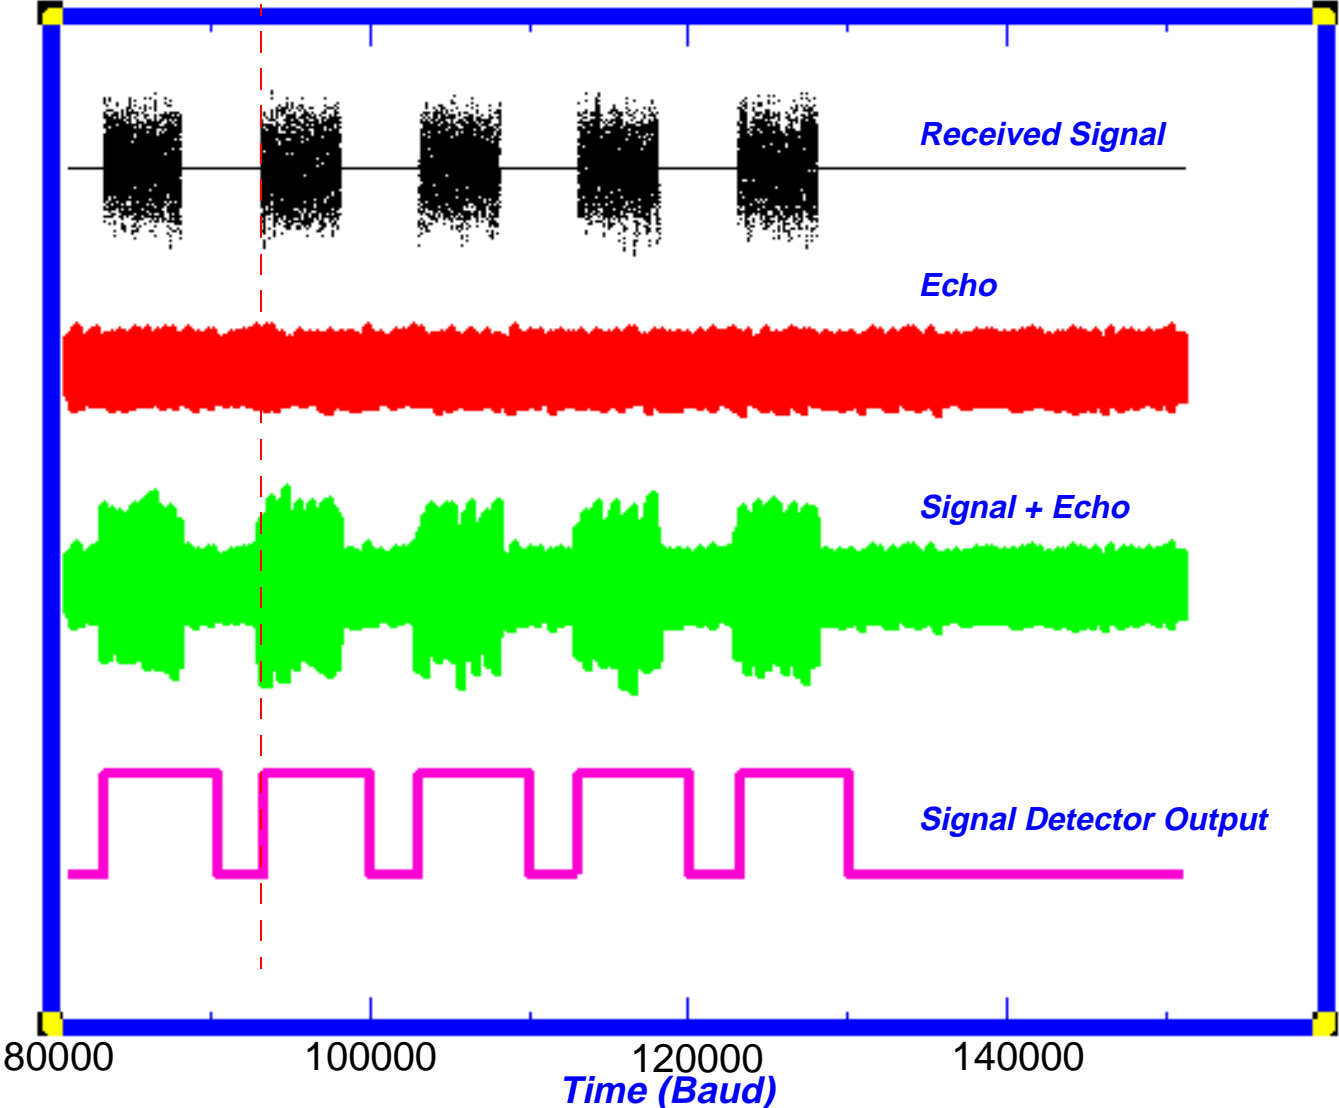

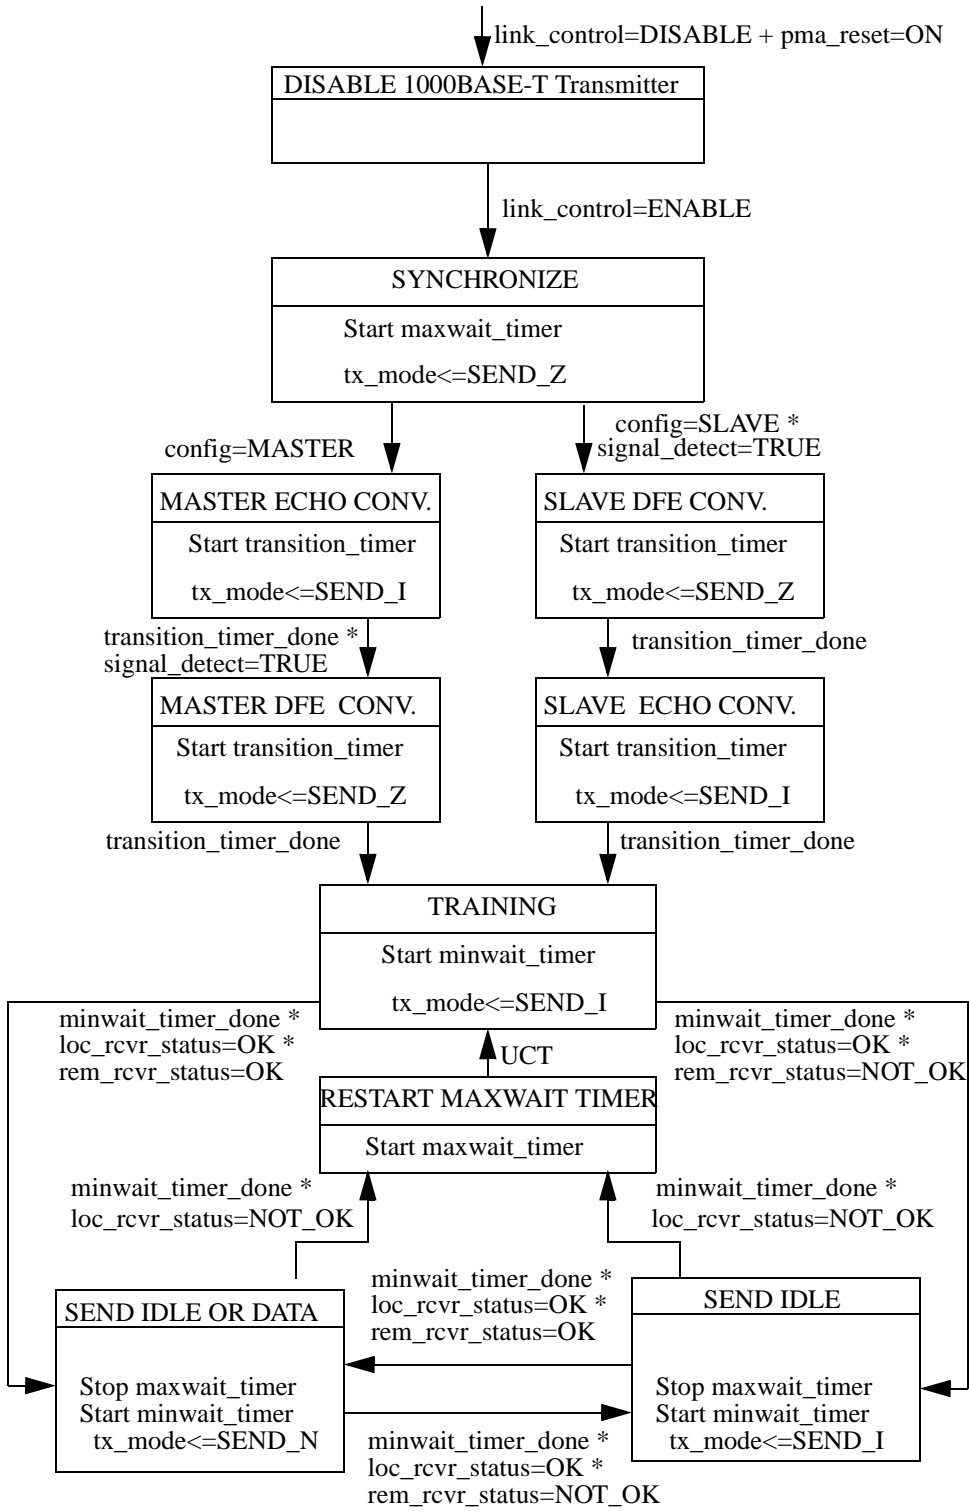

# Features of Simulation Environment

---

- **Complete handshake between Master and Slave is captured**
- **Fully asynchronous simulation, with 200ppm initial frequency offset between Master and Slave clocks**
- **All details of adaptive filter convergence and timing recovery (frequency and phase) captured**
- **Transmitter fully compliant with current draft (D1.2) of the PCS**
- **All startup sequencing is done automatically under PHY\_CONTROL**
- **Signal detector triggers transitions from Phase I to Phase II at the Master and from SYNCHRONIZE to Phase I at the Slave**

# Signal Detector Simulation Results

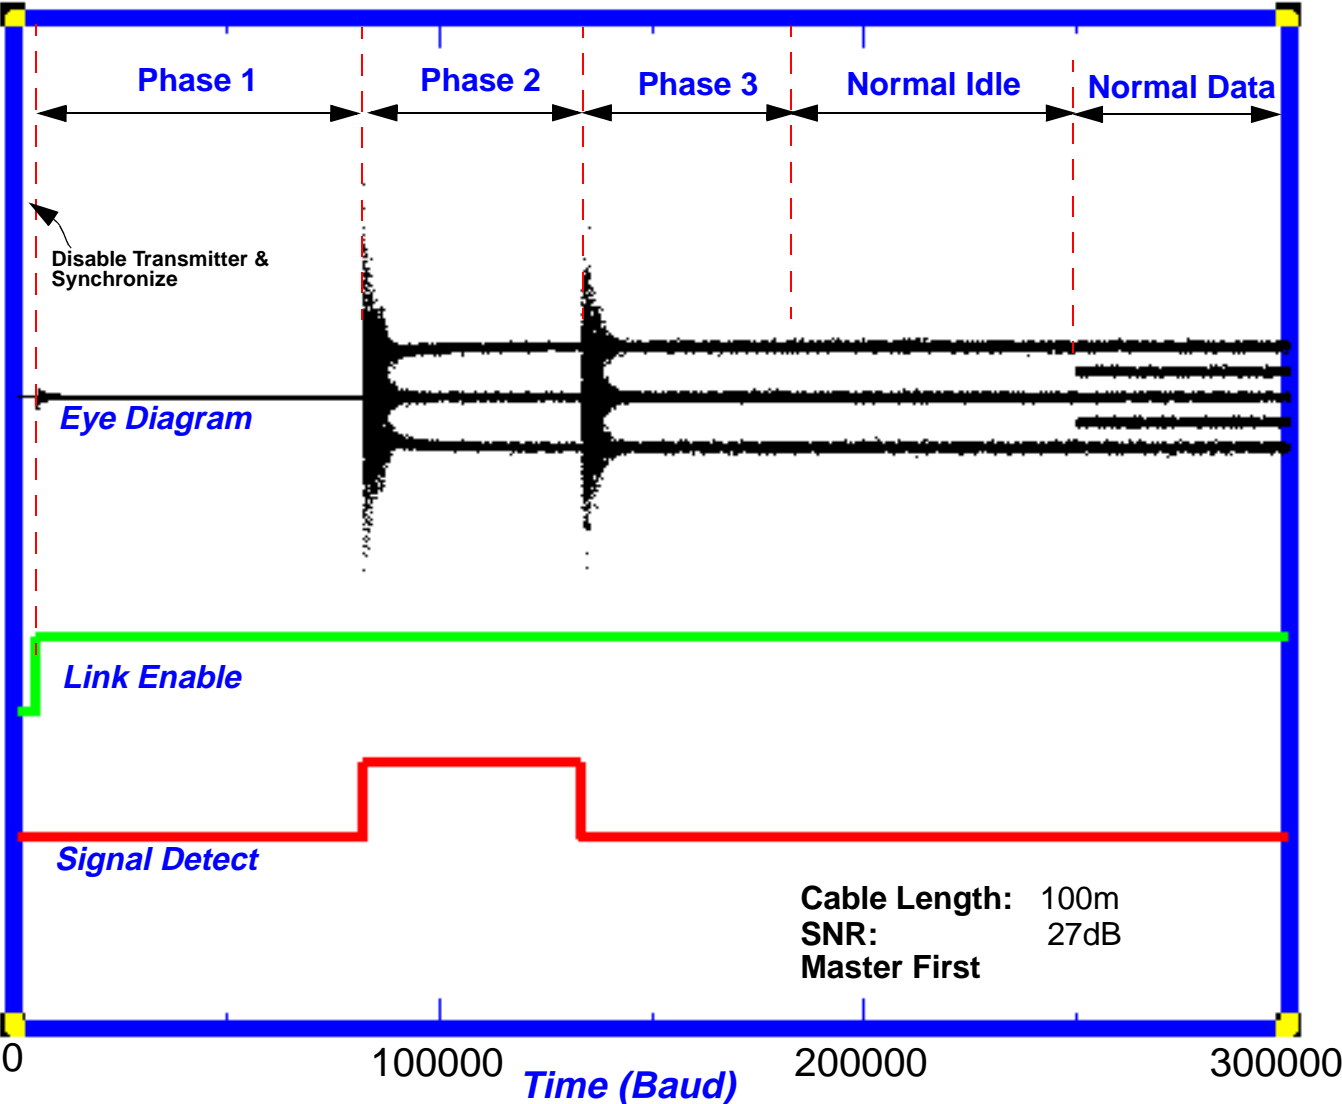

# Startup State Machine Cases Simulated

---

- **CASE 1: Master ends autonegotiation first. Cable length 100m. Normal SNR (27dB)**
- **CASE 2: Slave ends autonegotiation first. Cable length 100m. Normal SNR (27dB)**
- **CASE 3: Slave ends autonegotiation first. Cable length 100m. Low SNR (21dB)**
- **CASE 4: Slave ends autonegotiation first. Cable length 0m. High SNR (33dB)**
- **CASE 5: Slave ends autonegotiation first. Cable length 140m. Normal SNR (26dB)**

# Probability of Retries

---

- **Extreme noise conditions are required to cause false signal detect and a potential restart of autonegotiation during startup. (Noise must be greater than 350 mv peak and present simulatenously on all 4 pairs).**
- **Extreme noise can only restart autonegotiation by causing false signal detections if it falls in a window of less than 210 ms during startup.**
- **Noise within channel spec limits will not cause a retry of startup via autonegotiation**

# Extreme Scenario

---

- **Assume extreme noise spikes, exceeding spec limits, 32ns wide, at a rate allowing normal operation ( $<10^{-10}$  BER) are present.**
- **Assume noise spikes are present simultaneously on all four pairs so that a false signal detect can be generated.**
- **Assume that noise spikes of smaller magnitude that would cause interference with normal operation but not signal detect are not present.**

# Extreme Scenario (cont.)

---

- Then each spike would cause on average  $(1/2)*4*8=16$  bit errors. For a  $BER=10^{-10}$  the spikes would occur at a rate of one every 160 seconds.
- The probability that a spike would hit the 210 ms window during startup is 0.0013.
- Thus under unreasonably bad conditions and extreme assumptions, one out of about 1000 times autonegotiation would have to be restarted.

# Probability of Retry Conclusion

---

- **False signal detection causing retries of startup via autonegotiation are not an issue.**

# FLP Issues

---

- **Proposed signal detector rejects FLPs by requiring signal to be present on all 4 pairs before declaring `signal_detect=TRUE`. Since FLPs are generated on one pair, they will not result in `signal_detect=TRUE`.**
- **If a scheme for pair-insensitive autonegotiation is proposed which sends FLPs on all 4 pairs, signal detect should be modified to reject FLP pulses as follows.**

# Signal Detect for 4 pair FLPs

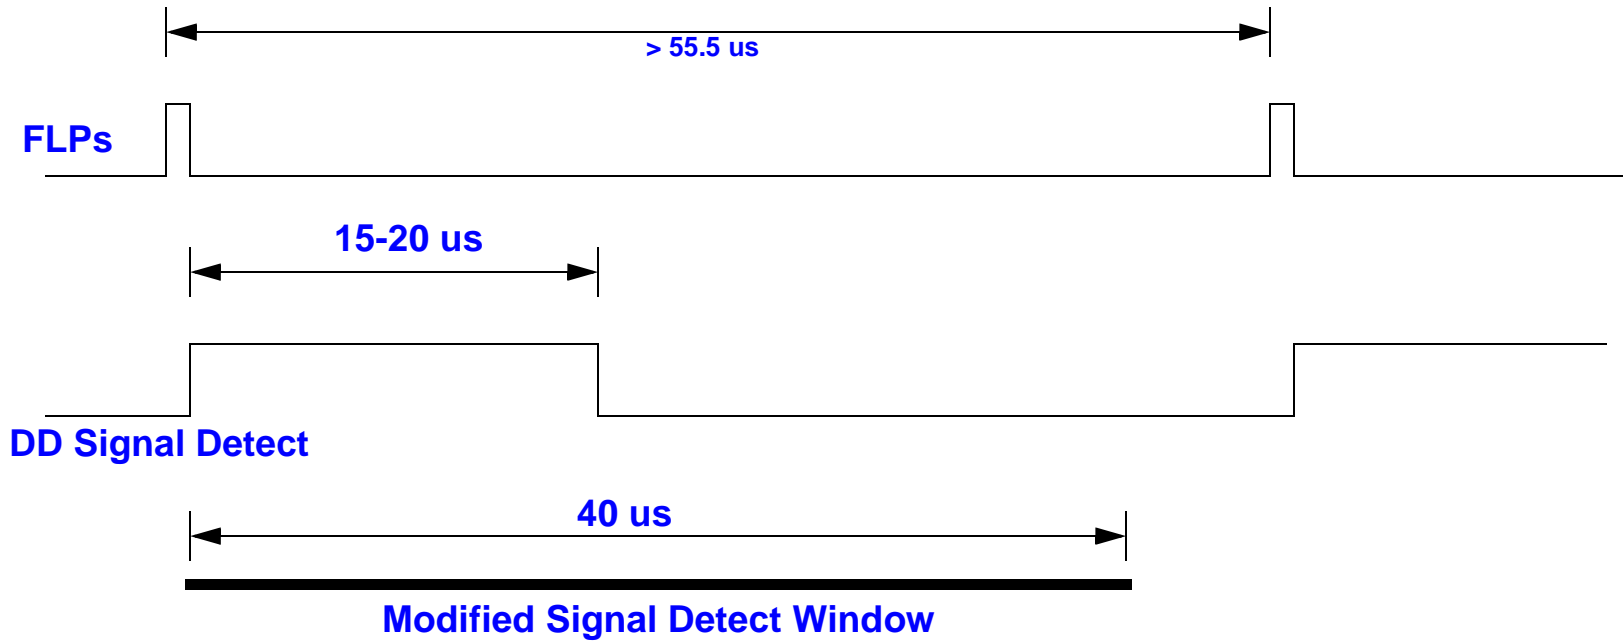

---

- Use Dan Dove signal detect as basis
- Additionally require that Dan Dove signal detect continuously indicate `signal_detect=TRUE` for 40 us before indicating `signal_detect=TRUE` to PHY Control
- FLPs have a nominal width of 100 ns and are separated by a minimum of 55.5 us so therefore will not trigger the signal detect.

# Modified Signal Detect Example

---

---

Modified Signal Detect

# Conclusions

---

- **Signal detector proposed by Dan Dove meets requirements of 1000Base-T and is very robust**
  - Insensitive to FLP pulses
  - With simple modification can accommodate autoselect
- **Startup state machine is fully consistent with startup protocol approved in Montreal**
- **Extensive simulations of startup state machine done**
- **Probability of restart is extremely small even under outrageous noise conditions**
