

Mario Puleo

Stressed sensitivity measurements with LiNbO₃ MZ and directly modulated sources

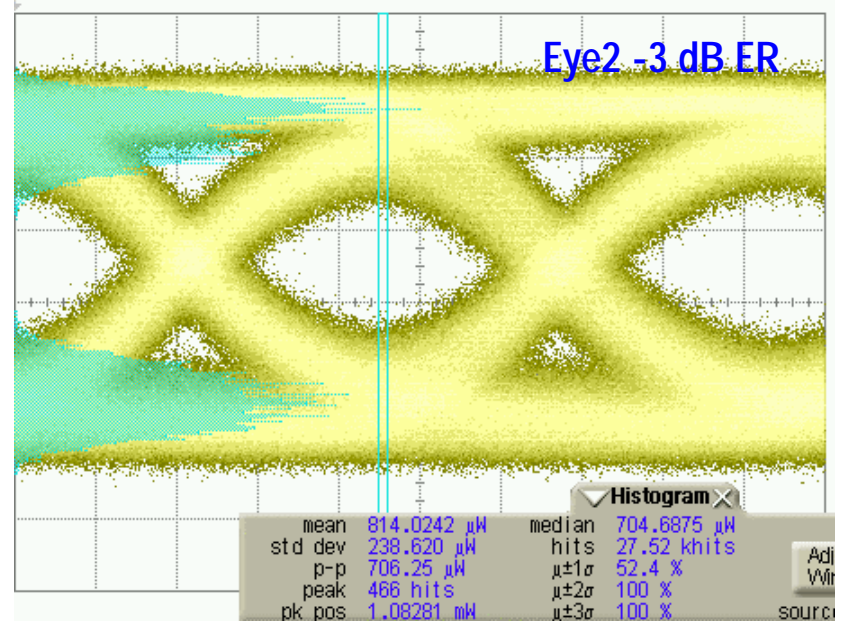

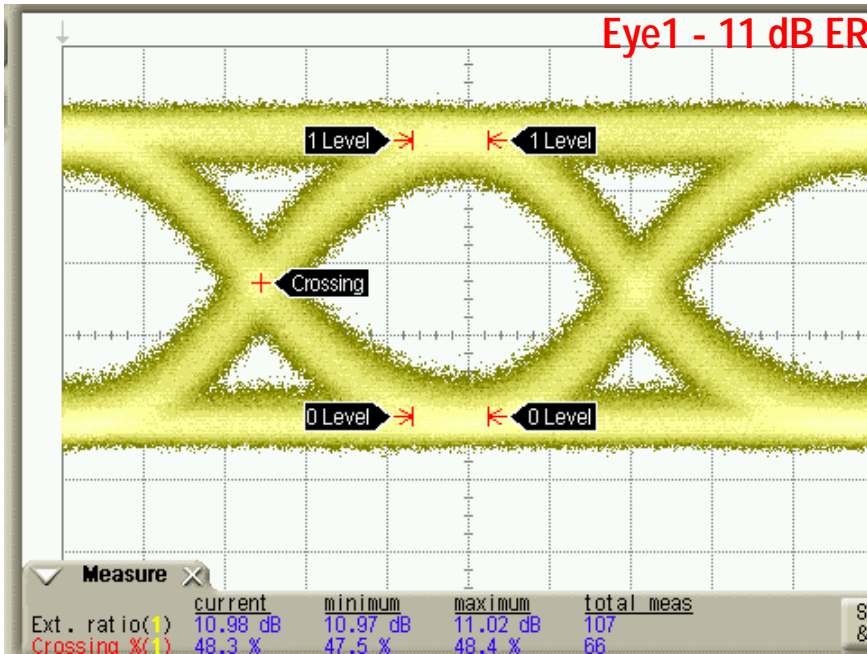

Agilent Technologies

Set-up

Effect of eye closure and extinction ratio

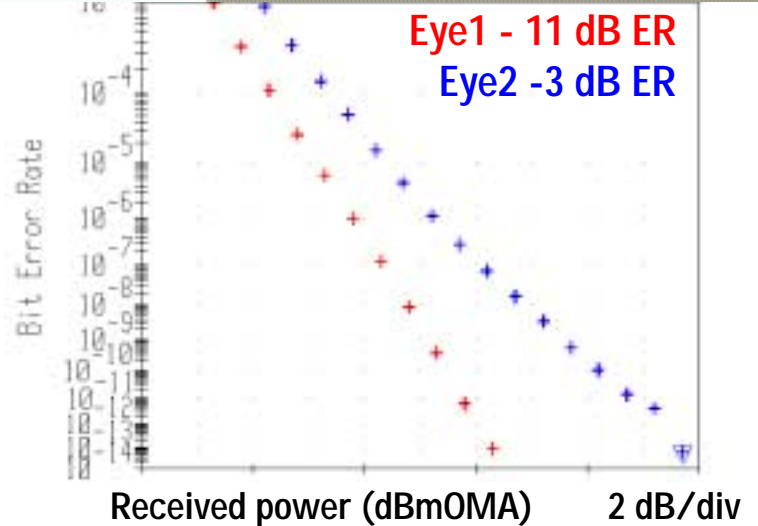

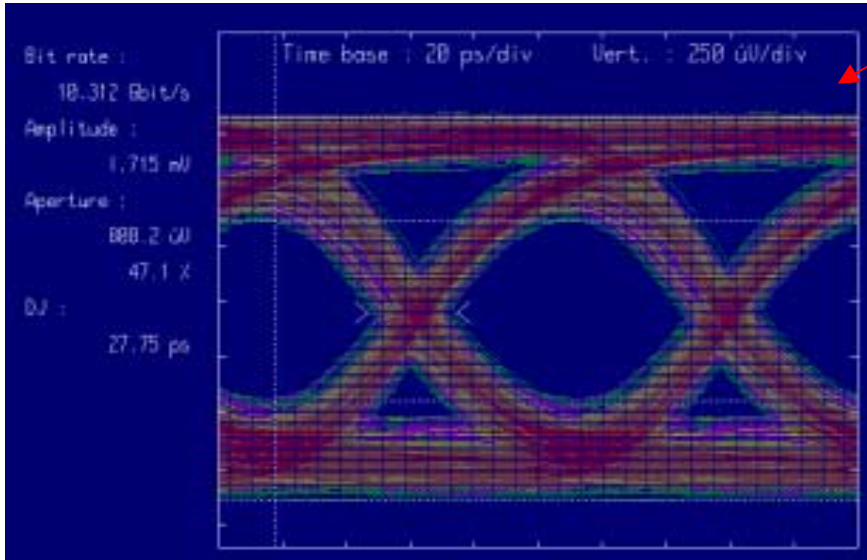

Eye closure obtained by undermodulating the LiNbO3 MZ,
 bad extinction ratio obtained by polarization misalignment at MZ input

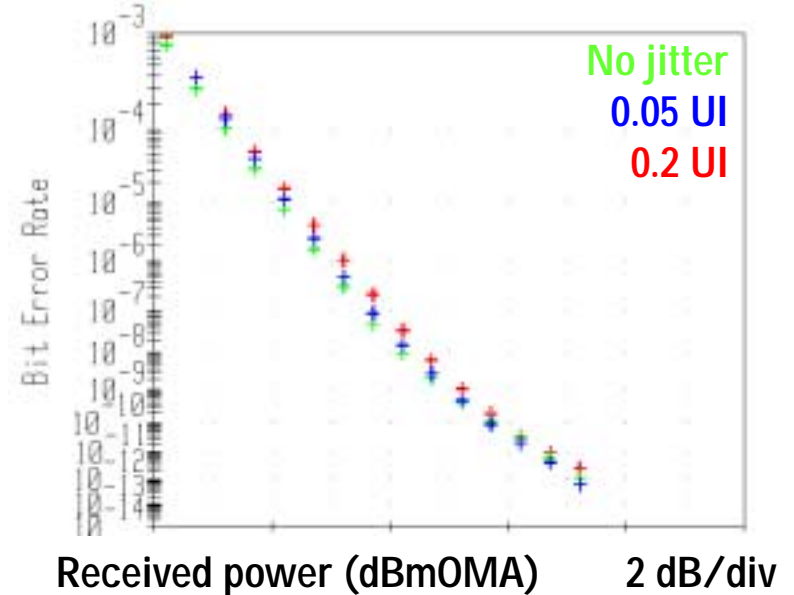

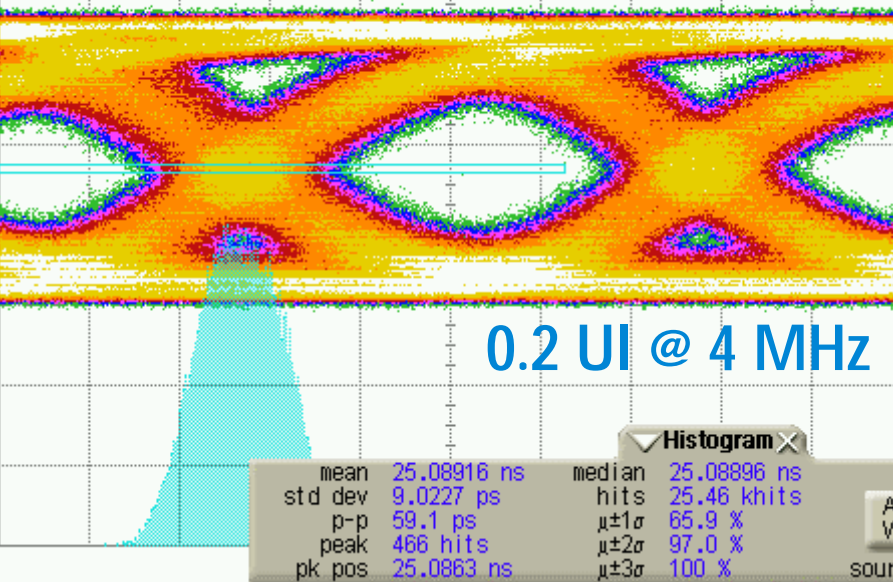

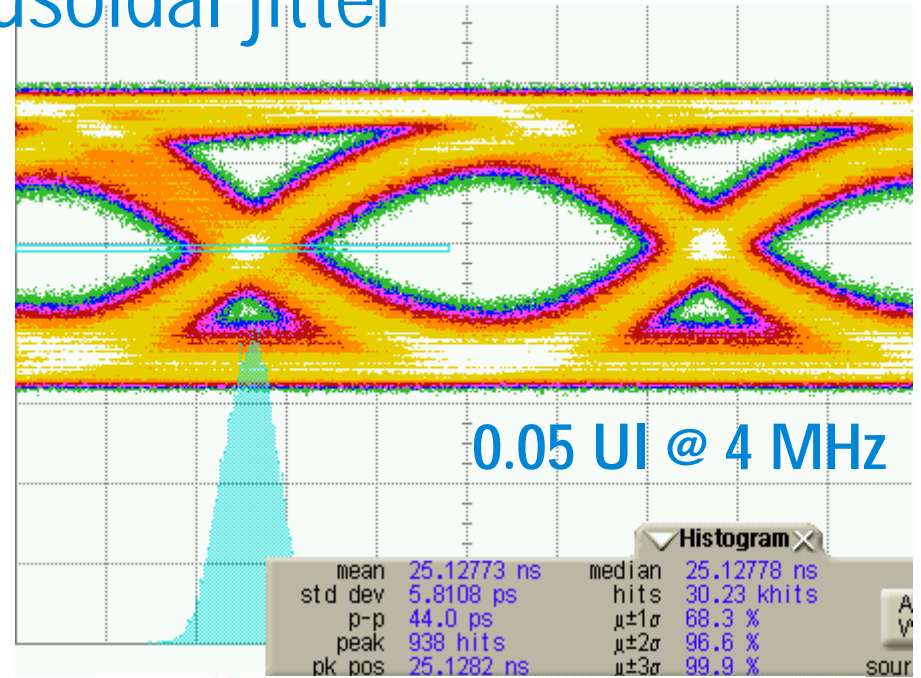

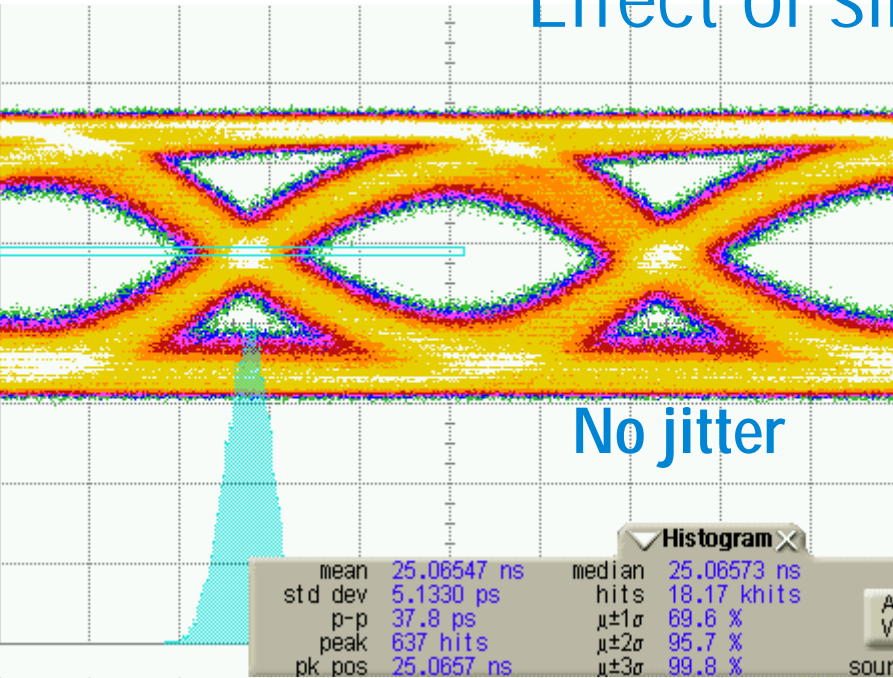

Effect of eye closure and extinction ratio

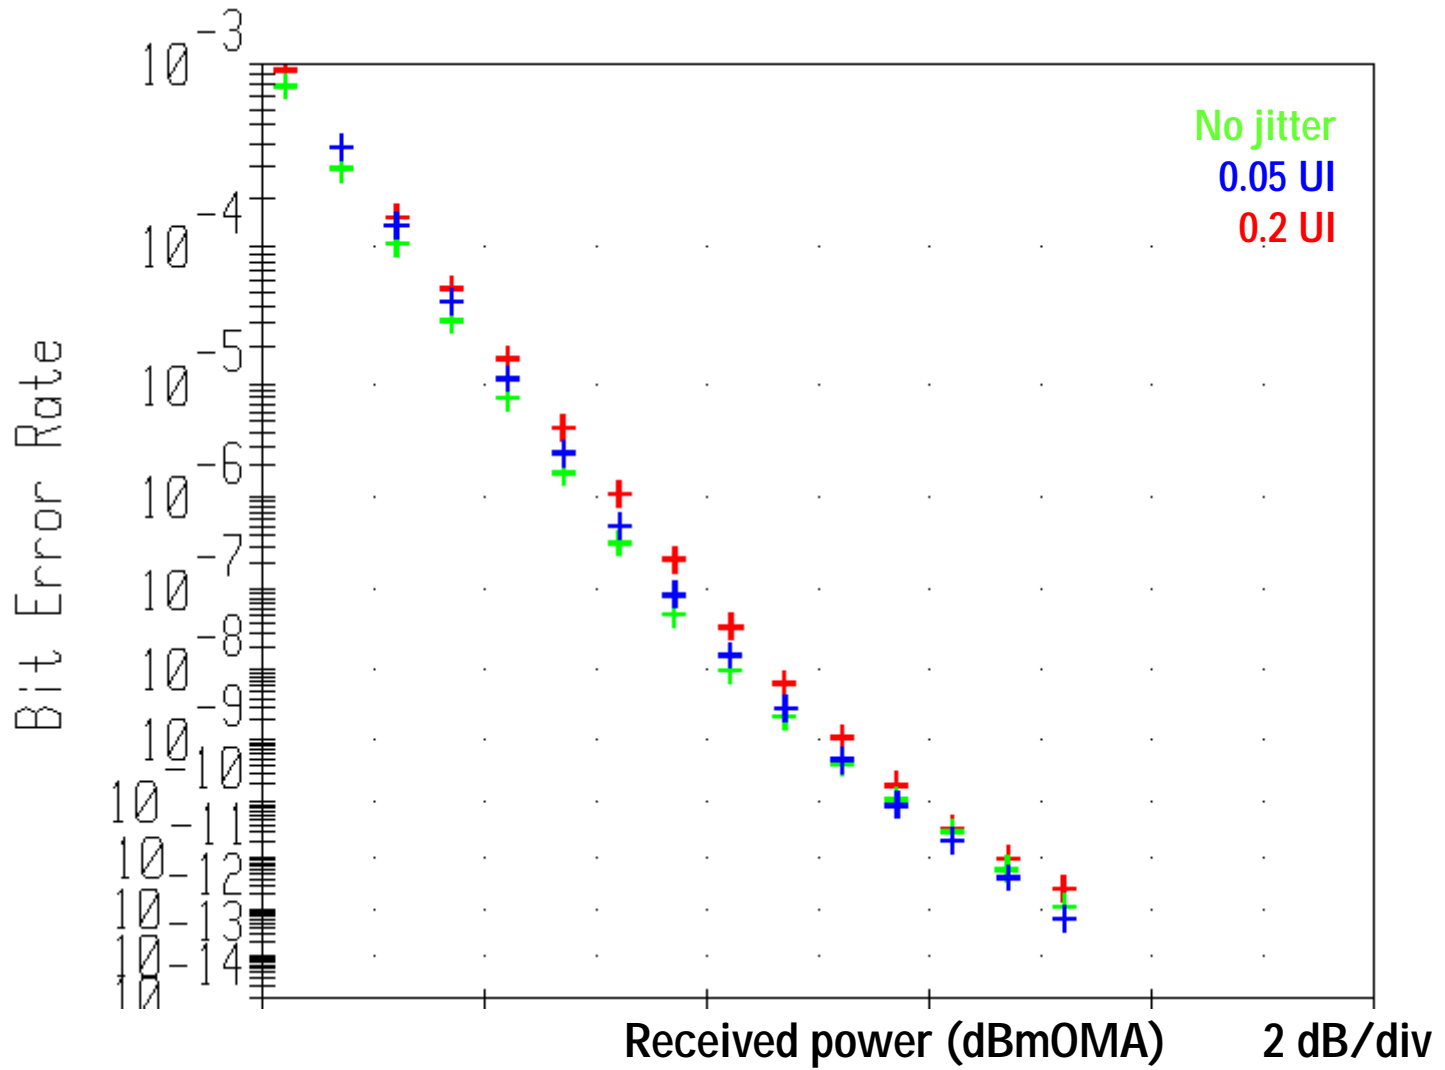

Same with eyeline

Effect of sinusoidal jitter

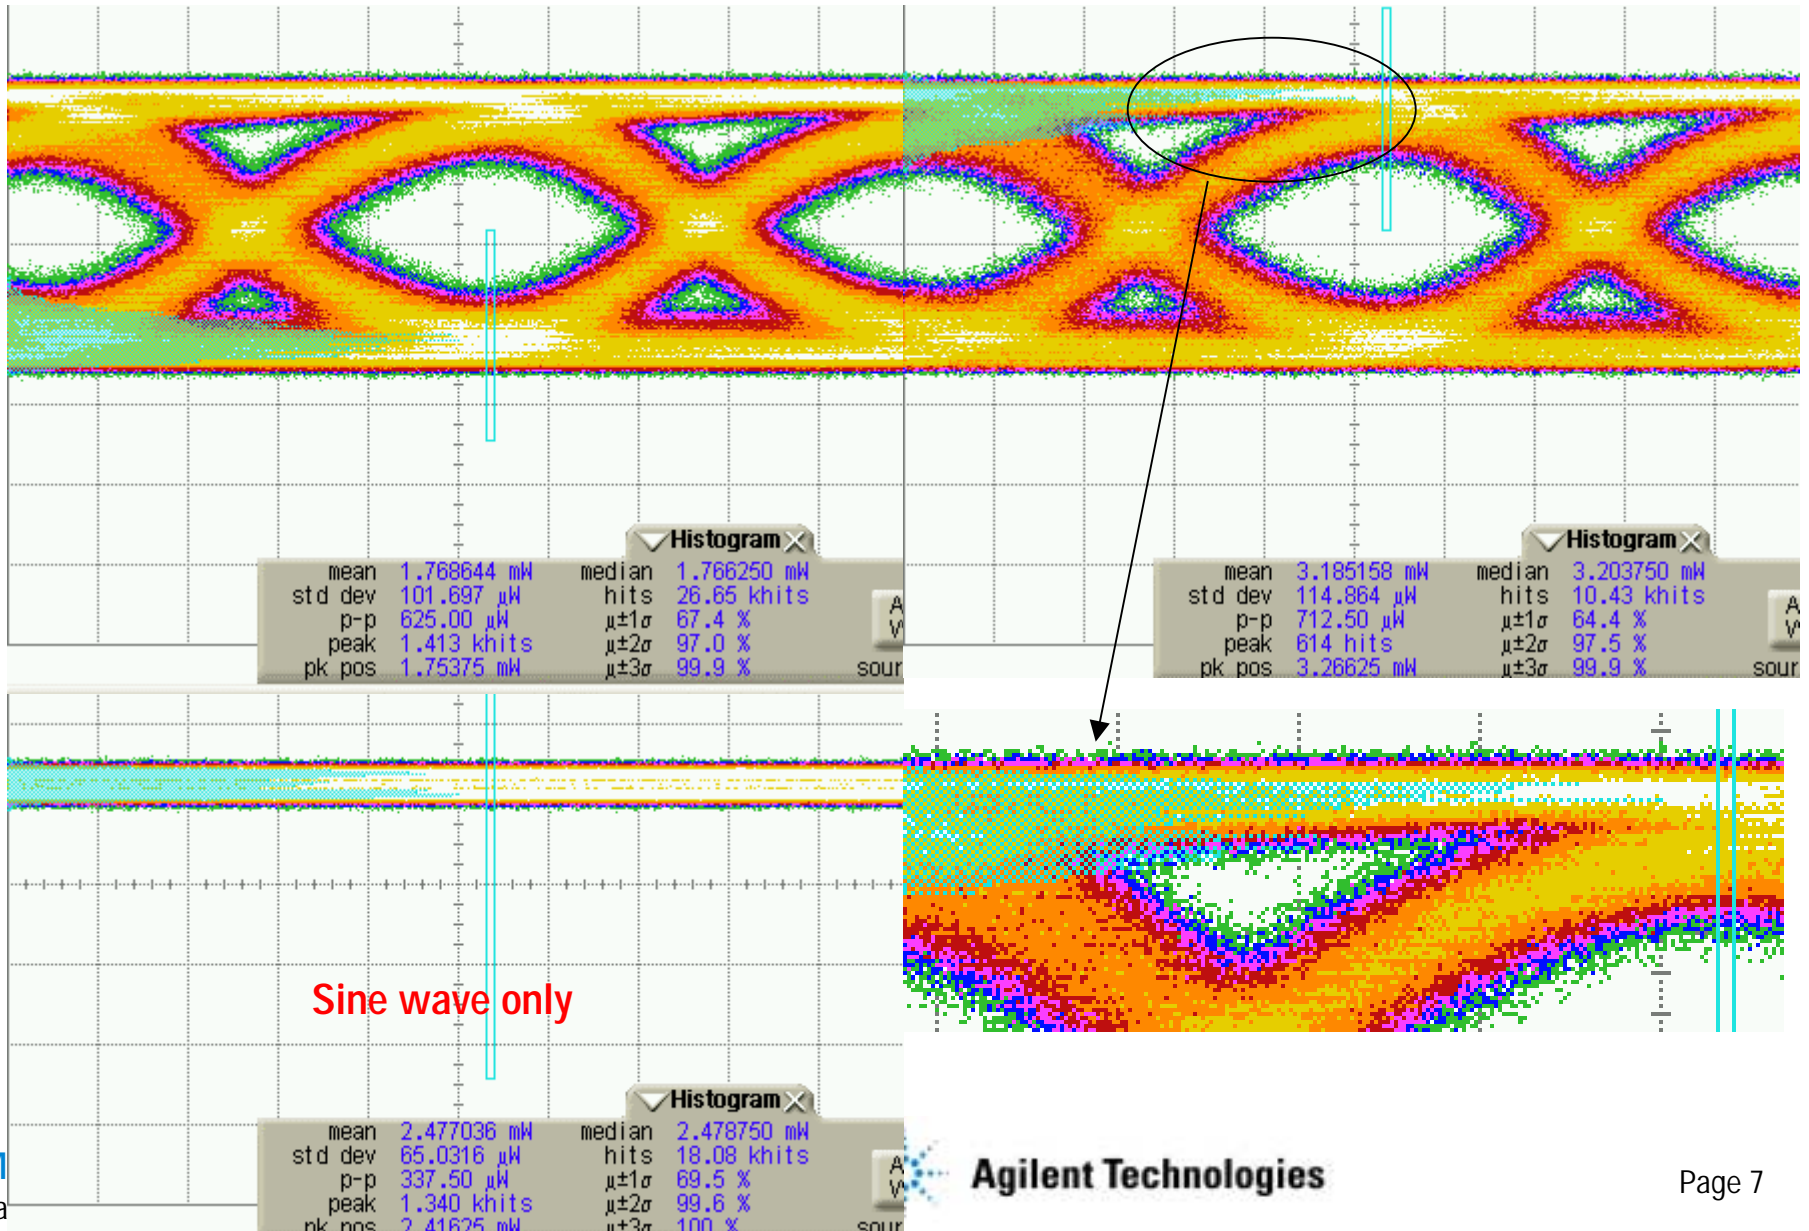

Same expanded

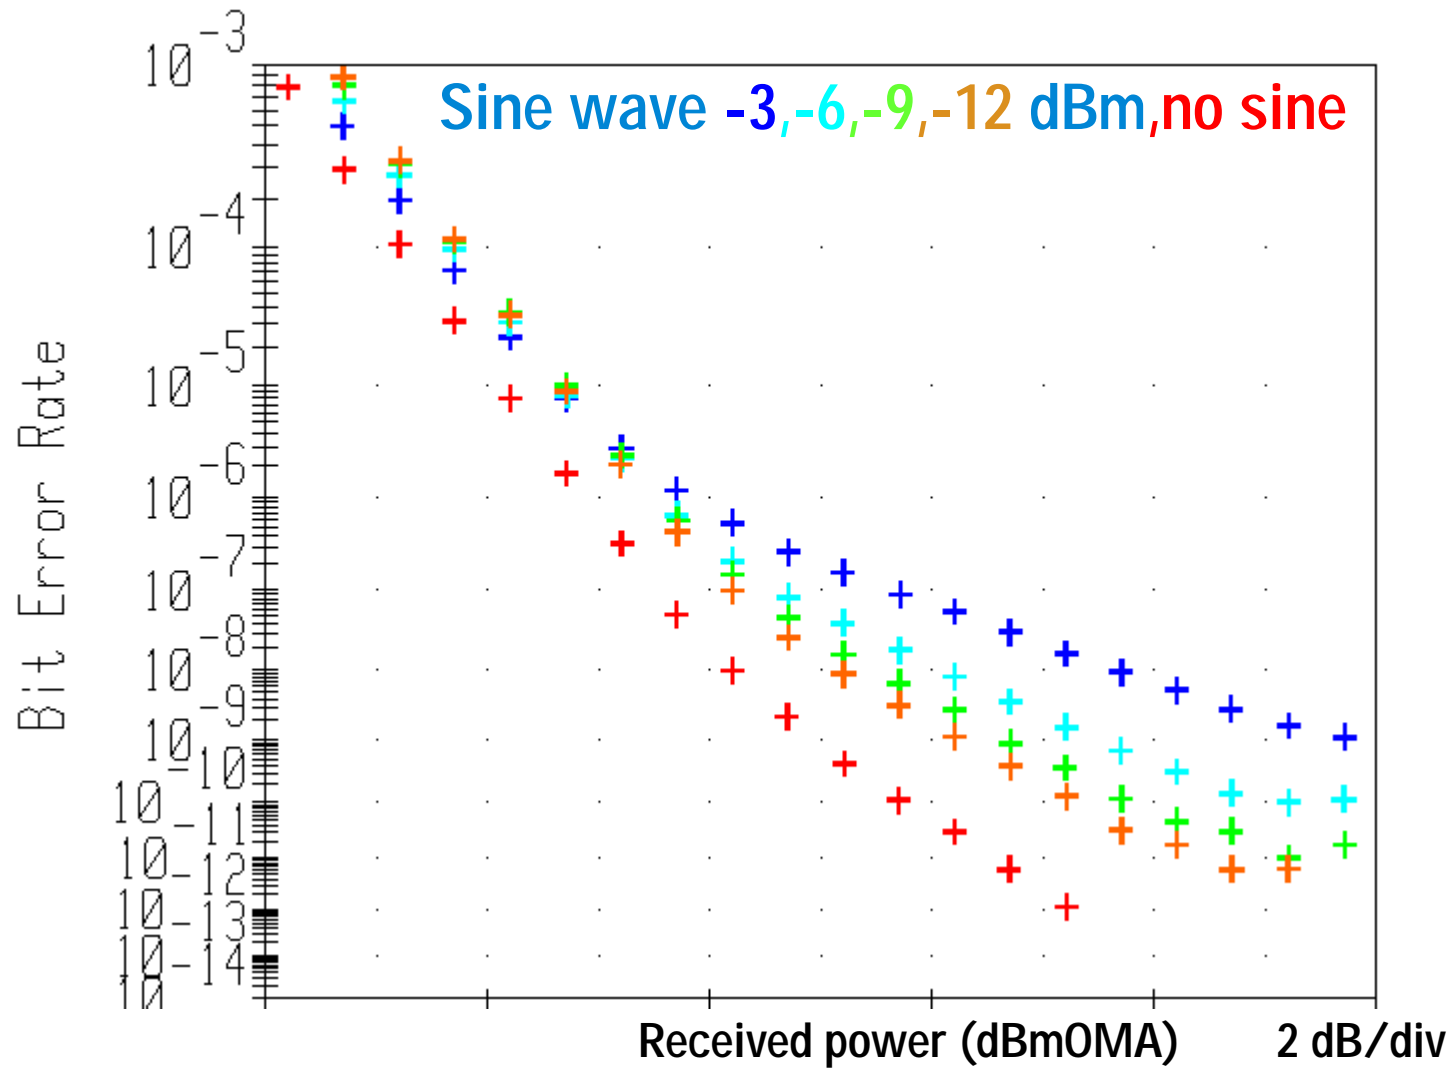

Effect of sine wave + sinusoidal jitter

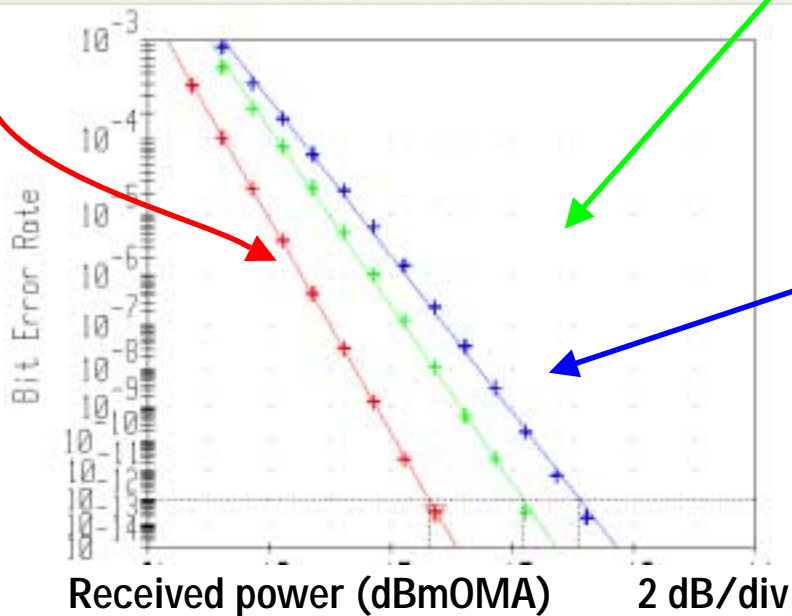

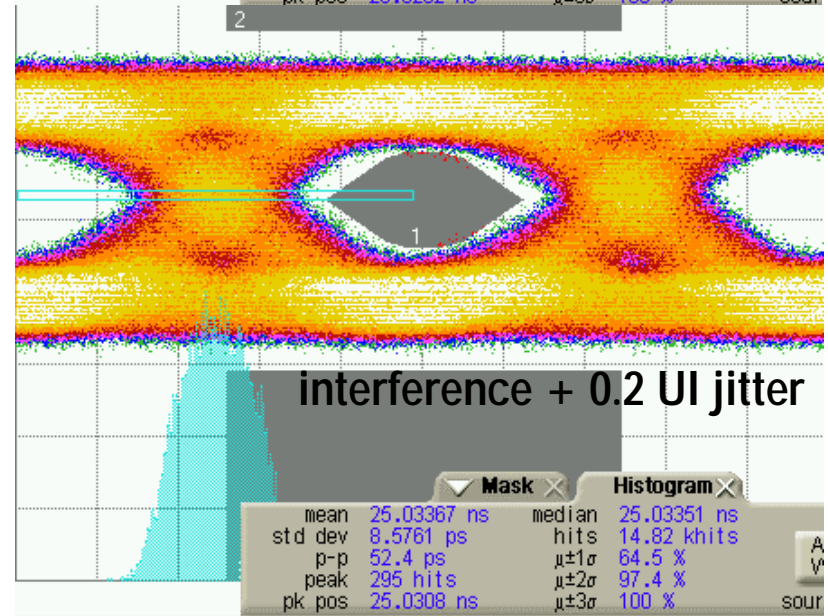

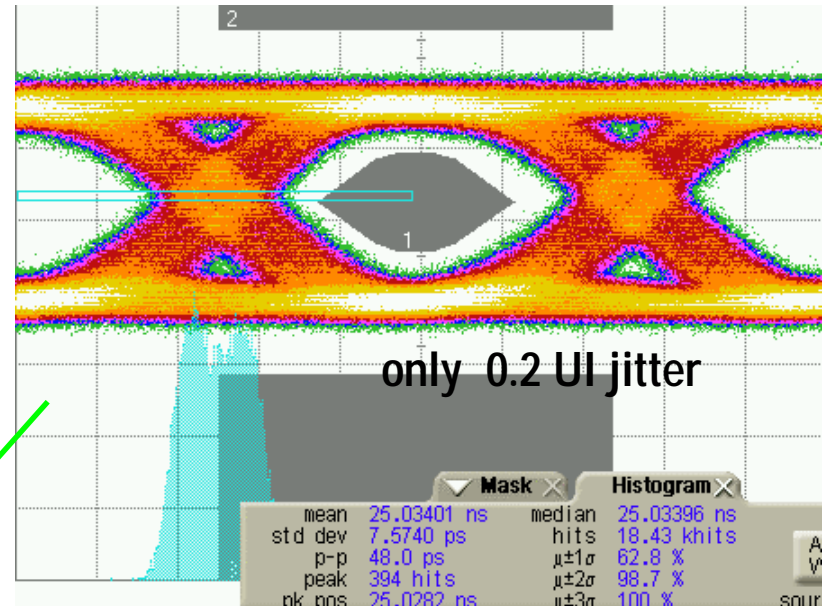

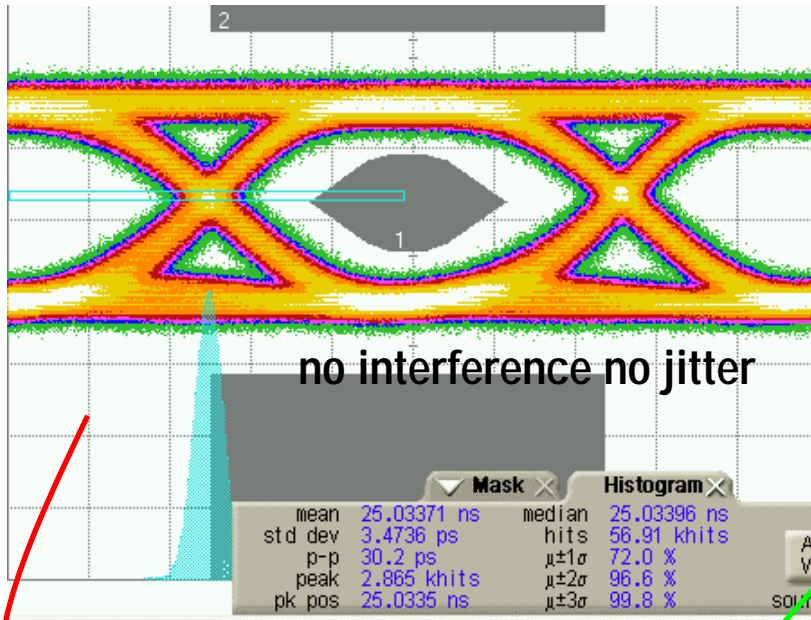

0.10 UI @ 4 MHz + sine -6 dBm @ 1 GHz

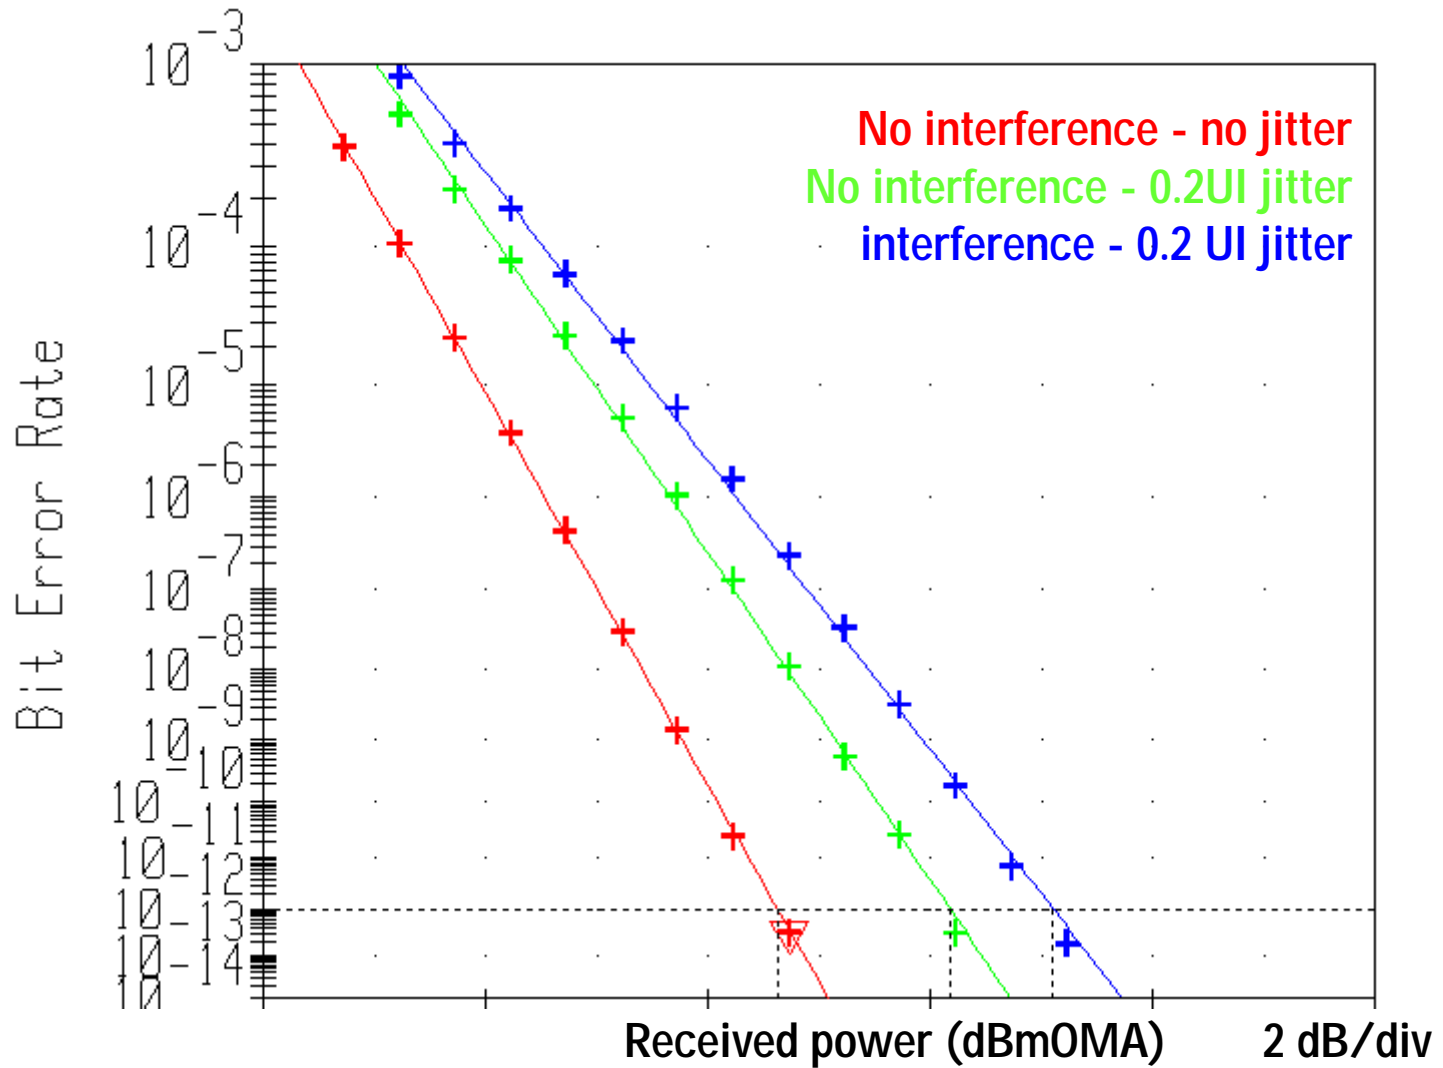

Effect of sine wave + sinusoidal jitter

Directly modulated 1300 nm source

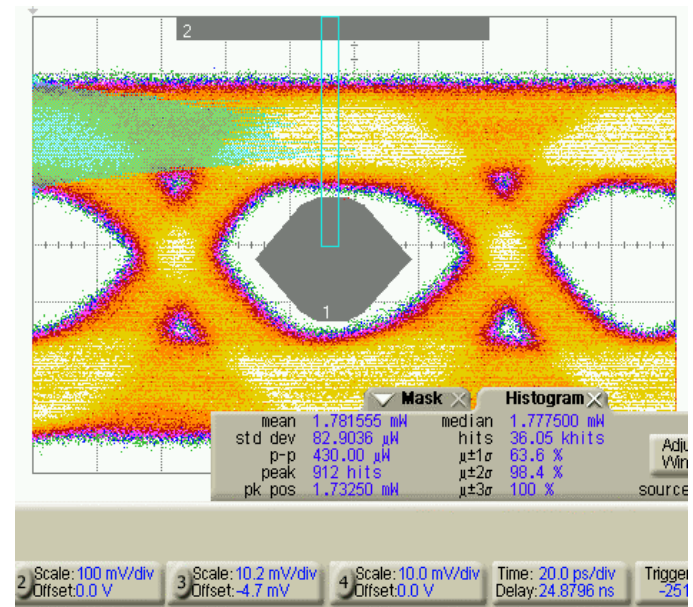

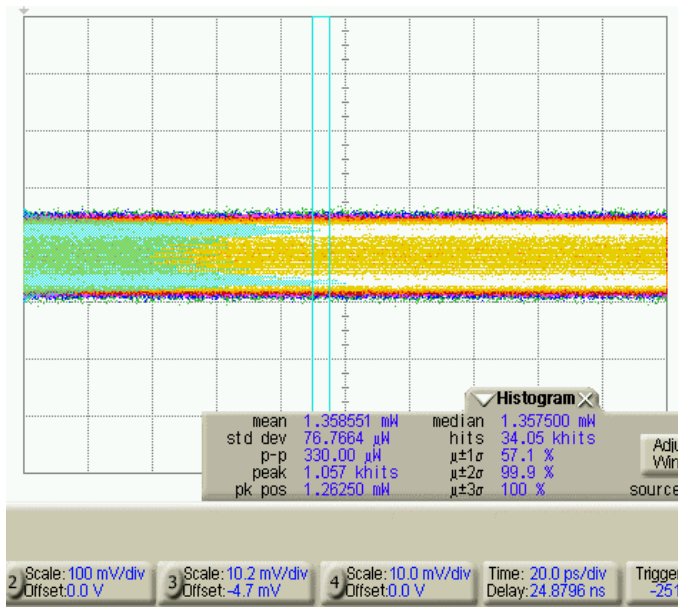

Same expanded

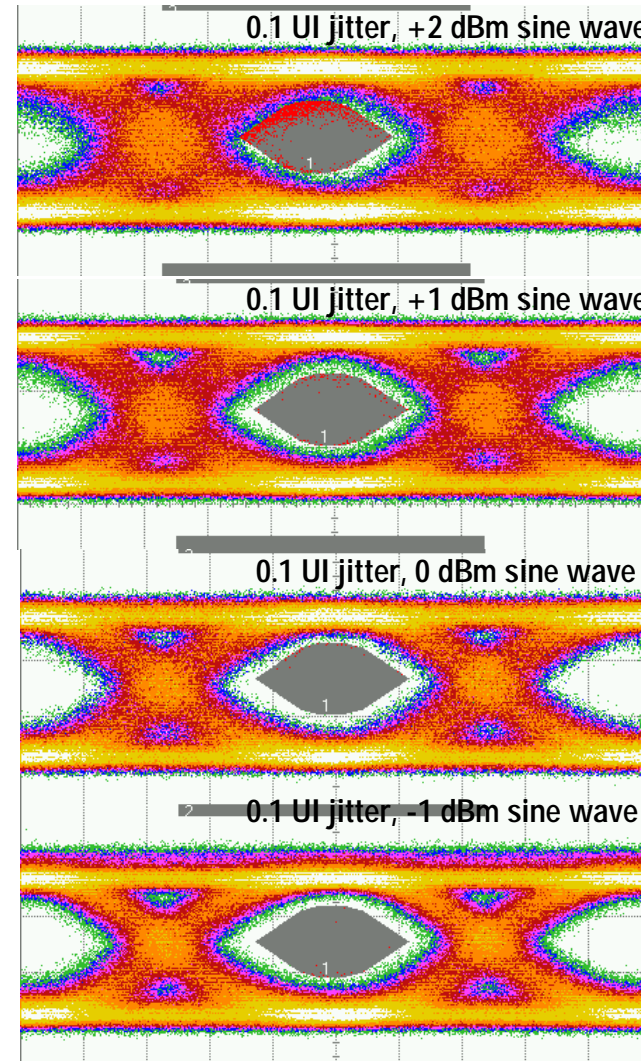

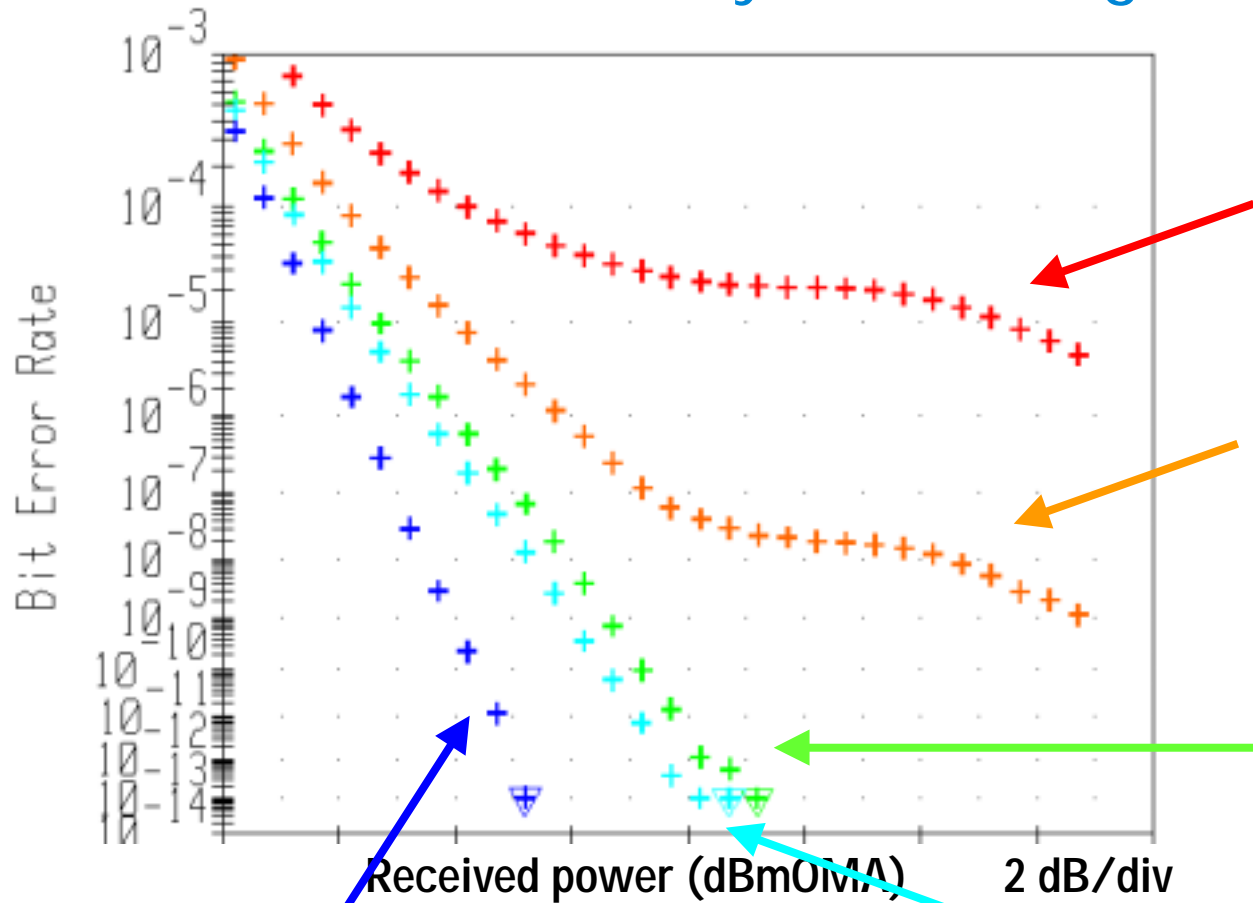

Directly modulated source

no data, no jitter, sine wave only

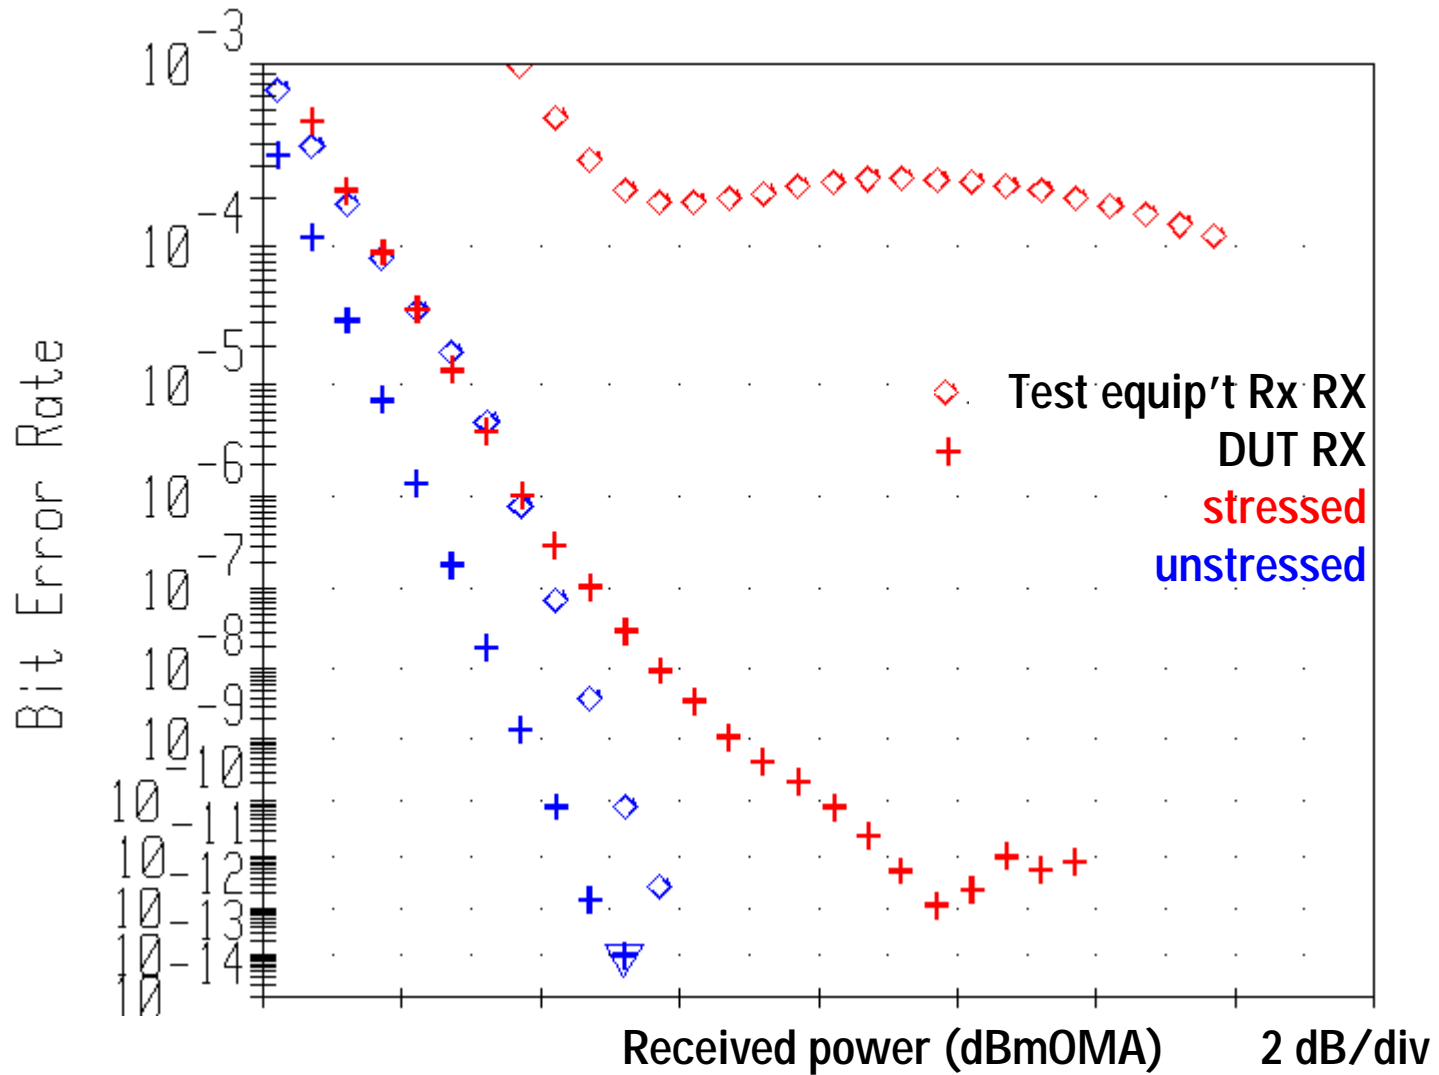

all

MZ driven over full dynamic range + sine wave + jitter

Other receivers are more affected by stressed eye

Conclusions:

Bad extinction ratio, DJ and ISI don't seem to give error floor problems, only penalty

Same for sinusoidal time jitter

Interfering sine wave very critical

With MZ TX used in linear region (small signal):
gives error floor even when it's nearly invisible in the eye.

With MZ TX used in limiting region (larger signal):
small differences in interferer pass from error free to error floor at 10^{-8}

With directly modulated laser :
gives penalty without floor even with ugly eye.

From test fest, receivers with higher tolerance have lower sensitivity
