### Comment Type TR Comment Status R

The success of 10GBASE-LRM as a standard is based on the ability of customers to purchase system components that meet the specifications in the standard, plug them together and have them work in a predictable, reliable and useful manner over the installed base of optical fiber. Since the installed base of fiber is not designed nor tested to support the alternative launch specified in the standard, I must recommend that the alternative launch be removed. This recommendation is consistent with the launch conditions specified in both 1000BASE-LX and 10GBASE-LX-4 and is the only known method to ensure predictable, reliable and useful operation of the link. The specification of two optical launch conditions that must be selected by the user in order to mitigate the risk of a link failing does not meet the level of quality and reliability associated with previous standards developed by 802.3.

### SuggestedRemedy

Replace "...The optical launch condition at TP2 is either the preferred launch or the alternative launch (at the user's choice), as specified in 68.5.1. A compliant PMD shall support both options. The launch is selected by using either a single-mode fiber offset-launch mode-conditioning patch

cord or a regular multimode fiber patch cord inserted between the MDI and TP2, consistent with the media type." with "...The optical launch condition at TP2 is specified in 68.5.1. The launch is selected by using a single-mode fiber offset-launch mode-conditioning patch cord inserted between the MDI and TP2, consistent with the media type."

Response

Response Status U

REJECT.

The Task Force has received input from delegates having experience with system vendors that a dual lauch will be acceptable to customers and is consistent with current practice.

Two launches are used to a) Cover the range of fiber types supported; and b) increase coverage statistics. The judgement of the committee is that the specification of Draft 3.0, including the launch details, will support the distances given in Table 68-2.

For: 12 Against: 2 Abstain: 2

Comment Type TR Comment Status R

Specify launch condition here consistent with 1000BASE-LX.

### SuggestedRemedy

Add the following text above Table 68-2: "To ensure that the specifications of Table 68-2 are met, the 10GBASE-LRM transmitter outputs shall be coupled through a single-mode offset-launch mode-conditioning patchcord, as defined in 38.1.4 for all fibers except OM-3, which uses a regular patchcord."

Response Response Status U

REJECT.

Adjust the maximum channel insertion loss consistent with the actual supportable distance using 1.5 dB/km times the cable attenuation plus the 1.5 dB allocation for connectors. The values that support the 220m length are 1.83, 1.83, 1.83, 1.65, and 1.83 respectively but may need adjusted based on the recalculation of supportable operating ranges.	The specification of TWDP allows penalties 0.5 dB or more worse than that which the reciever is tested based on the current stressors specified in Table 68-5. This implies that the transmitter can produce channel outputs that exceed the level of stress that the receivers are specified to accomodate.
SuggestedRemedy	SuggestedRemedy
Replace the current values with those based on the supportable operating ranges. The	Replace "4.7" with "4.2"

### Comment Type TR Comment Status R

The presentation by Lindsay et al (Lindsay\_1\_1105) at the November 05 meeting shows that the connector loss experienced in a link with laser launch is significantly less than expected from the overfill connector loss spec, resulting in a 0.9dB unallocated margin. In addition if the TWDP of the Tx is not at the maximum value this margin is even larger. Relaxation in the minimum OMA/Average power of the Tx (and potentially linking it to the TWDP of the Tx) would result in easier to manufacture (lower cost) Tx's.

### SuggestedRemedy

Option 1. In table 68-3 change Launch Power in OMA min to "-5dBm" and Average luanch power min to "-7dBm" Option 2 In table 68-3 change Luanch power in OMA min to "-6dBm" and Average launch power min to "-7dBm". Add an additional link "Launch power in OMA min -9.7dBm + TWDP". In table 68-4 change Lowest power in OMA to "-7.4dBm" For both options. Change Figure 68-5 to reflect the new numbers (figures are available for presentation). Add an informative foot-note to table 68-4 referenced from Lowest power in OMA and Lowest average power. "Note that the connector loss experienced in a link with laser launch is less that the specified connector loss which is measured with overfill launch. This results in the minimum receiver input power being greater than the minimum transmitter output power minus the overfill connector loss.

Response

Response Status U

REJECT.

Straw poll 1: There is margin within the link budget. Agree: 14 Disagree: 1 Abstain: 2

Straw poll 2:

There is margin within the link budget AND that we will use it to reduce the tx OMA (min) and tx ave power (min) by 0.5dB, or less. Agree: 6 Disagree: 12 Abstain: 0

### Straw poll 3:

We will allow a trade off between lower TWDP value and tx OMA (min). Yes: 4 No: 10 Abstain: 2

#### Reject with explanation:

The consensus within the committee is that margin within the link budget should not be used to reduce the tx power in OMA. This consideration includes the margin resulting from

### Comment Type TR Comment Status A

The jitter tolerance test values in Table 68-5 are not adequate to test for the equivalent of the maximum uncorrelated jitter allowed in the Tx.

SuggestedRemedy

In table 68-5 change jitter frequency and peak to peak amplitude from (40,5) to (80,5) and (200,1) to (400,1)  $\,$

For test transmitter signal-to-noise ratio Qsq[sup]b, no type or units are given, a possible source of confusion, as SNRs can be specified in either logarithmic form (decibels) or in linear form (a dimensionless ratio).

SuggestedRemedy

Suggest adding the phrase "linear ratio" or the like to the Unit block.

### Comment Type TR Comment Status R

At the time that the IEEE 803.3ag study group was formed, the situation in the market for transceivers to serve the installed multi-mode fiber infrastructure was substantially different that it is today. Due to the collapse of the "telecom bubble," the supply base for 10GBASE-LX4 modules had become unstable by the time of the November 2003 LRM CFI. Per the CFI material presented by Tolly, there was a "lack of broad market availability from multiple vendors of 10GBASE-LX4&". The situation today is dramatically different than it was when the 802.3ag study group was formed. Tens of thousands of 10GBASE-LX4 modules have shipped from multiple vendors. A larger base of vendors has formed behind these to provide components. Broad market potential is being achieved. Introducing another PMD with substantially similar capabilities to 10GBASE-LX4 may not further promote the 10 Gigabit Ethernet Market, it could rather create market confusion that will further delay the broad deployment of 10 GbE systems and hurt the companies that have invested tens of millions of dollars to bring 10GBASE-LX4 technology to the market. Furthermore, the "distinct identity" of LRM is on weak footing. A key premise behind the "distinct identity" claim for 10GBASE-I RM is that only I RM modules can be made with a serial electrical interface. This is not the case. With the availability of XAUI to XFI ICs having power dissipation comparable to the EDC ICs required in 10GBASE-LRM transceivers, 10GBASE-LX4 modules can also be made with a "serial" XFI electrical interface. Smaller optical multiplexing and demultiplexing components are also now commercially available, allowing compact Tx and Rx optical subassemblies that can fit into very small form-factors.

### SuggestedRemedy

No change is proposed. The sponsor ballot pool should be made aware of these issues through the normal comment resolution process so that they can make the most informed vote.

Response Response Status U

REJECT.

Draft 3.0 of the specification has received 87% approval by the Sponsor Ballot pool.

The consensus within the Task Force and Working Group is that 10GBASE-LRM retains both distinct identity and broad market potential.

Further, to address the commenters remark about the investment in LX4, considerable resources have now also been invested in development of 10GBASE-LRM technology, reinforcing belief in this standard within the industry.

The comment, together with this response, will be recirculated - meeting the wishes of the commenter.

### Comment Type TR Comment Status R

It is well known that the stability of the transfer function of multi-mode optical fiber is very poor for a center launch. Polarization effects have also been shown to have a significant impact on the channel characteristics when an offset launch is used (see Fiedler\_1\_0904). While the IEEE 802.3aq task force has done an outstanding job in modeling the static impulse response of fibers thought to be representative of the installed base, the study of the dynamic response of the channel has been more limited. While the work presented in King\_1\_1104 and Cunningham\_1\_1104 has been a good starting point, an exhaustive study of the dynamic characteristics of the multi-mode fiber transfer function in a broad set of fibers has not been conducted. It has not been conclusively proven that changes in the fiber impulse response will be limited to the 10's of Hertz rate. There is a strong risk that performance problems will be observed in the field on links at or near the maximum operating distances specified in the standard. Even if dynamic effects were fully understood and modeled, the document does not define an adaptation rate required for the EDC IC to track changes in the fiber impulse response or a standard test for the speed of adaptation.

#### SuggestedRemedy

Specify a minimum rate of adaptation, and define a test for verification of compliance.

Response Response Status W

REJECT.

One outcome of the detailed work within the 802.3aq channel ad hoc Task 2 sub-committee was that all significant variations in fiber responses are expected to occur at frequencies less than 10Hz. This result may be found in king\_1\_1104. The consensus within the Task Force is that such slow rates of change will not challenge the adaptation speed capabilities of any practical adaptive equalizer. As the comprehensive stressed receiver test will pass only adaptive equalizers, a separate dynamic test would be redundant (as well as being complicated and expensive to implement).

Further, the committee has had some feedback from the Ballot Pool that the existing receiver compliance test in too complicated. - See comment 34.

### Comment Type TR Comment Status R

"Quasi-Static" Dynamic Response: A second type of dynamic response identified by the 802.3aq LRM task force and documented in presentations and previous comments is the quasistatic variation caused by touching or twisting or adjusting the fiber and/or connector. The modeling used to estimate the modal power distribution for near-center launches does not include this effect, nor does it agree with actual measurements presented by Corning, OFS, and Big Bear Networks. The resulting analysis gives an optimistic estimate of possible problems with OM1 and OM2 fiber.

### SuggestedRemedy

The estimated failure rate in simulations with near-center launch needs to include an more realistic MPD consistent with worst case MPDs seen as the connector is twisted. In order to keep the supported length at 220m, this will require changing the 'stressor' or tap weights in Table 68-5 for the receiver and in the TWDP code for the transmitter. This work should be done rigorously to the satisfaction of the task force. The proposed change is to shift the three indicated stressors each one "place" further down the table previously calculated by J. Ewen.

Response Response Status U

REJECT.

In a simulation of the consequences of optical behavour mentioned in the comment, approximately 0.06dB difference ISI stress (PIE\_D) levels is predicted. This is not considered, by the committee, to be significant enough to justify changing the document at this time.

CI 68	SC 68.5.3	P <b>27</b>	L 25	# 70
ABBOTT	. JOHN S	Individual		

### Comment Type TR Comment Status R

The index perturbations for OM1 and OM2 fibers are significantly different. OM1 fiber is optimized for 1300nm, while OM2 fiber can be either 850- or 1300-optimized. The result is that the supported length, the stressors, and the failure probability cannot all be the same. What is likely is that OM2 fiber meeting the minimum OFL criteria and optimized for 850nm will have a significantly higher failure rate. The stressors need to be adjusted to take this into account, or the supported lengths for OM1 and OM2 need to be different.

### SuggestedRemedy

Supported length and/or stressors for OM2 fiber need to ensure that the link will work regardless of the 'type' of OM2 fiber installed (i.e. 1300nm-optimized, 850-optimized, or generic dual window). Divide the OM2 'distribution' approximately into thirds (1300-, 1075-, and 850- optimized) , and determine the stressors necessary for each third to meet the supported length. Use the most conservative.

Response	Response Status	ι
REJECT.		

The consensus view within the committee is that convincing evidence has not been provided that the Draft 3.0 ISI generator parameter values are not adequate to support the distance given in Table 68-2 for OM2.

The ISI stressors are chosen to stress the receiver performance for families of different stress types, and are designed to cover the different fiber types.

Regarding the subset of fiber manufactured as OM3 that does not meet the OM3 spec and is re-classified and sold as OM2: This is likely to have less stressful ISI response for offset launch than OM3, and is expected to have good performance with center launch.

An agreed calibration of the OM2 model stats with the link performance of the intsalled base has not be presented. This model predicts very pessimistic results when compared with existing link standards.

See ewen\_1\_0905 and abbott\_1\_1105, in particular slide 13 in the Abbott presentation.

### Comment Type TR Comment Status R

The committee recommendation to the resolution of comment 166 to Draft 2.0 (John Abbott) was to make the TP2 stressors 0.07dB greater than TP3 stressors, to account for the effect of the laser being at 1355nm rather than 1310nm.

### SuggestedRemedy

Modify the stressors for TWDP (i.e. TP2) per the committee recommendation. This may require recalculation of the Ewen "table" to a finer PIE-D spacing to enable a more exact shift of the stressors.

Response Response Status C

REJECT.

The note, referd to by the commenter, included in the response to comment 166 on Draft 2.0 was an aknowledgement, by the committee, that a recommendation has been made. It was not an acceptance of that recommendation.

That recommendation was calculated based upon a link length of 300m, and the then current comp. stressed rx test definition. Values consistent with the present test definition would be smaller and the effect is not considered significant enough to warrant a change to the document.

operating range for 400/400 fiber was just a guess. Simulations with different lengths suggest that a PIE-D of 4 corresponds to 320MHz.km at 100m, and 400MHz.km at 120m. Hence either 100m can be considered conservative or we should be able to increase length to 120m. SuggestedRemedy	We are planning this standard to apply to FP lasers, DFB lasers, and 1300nm VCSELs. The "RMS spectral width" does not adequately characterize the laser. See Derickson p. 27 or Senior 2nd edition p. 403. We should use FWHP and ideally do some modeling/experimentation showing the effect of spectral width. Figure 68-3 assumes a Gaussian spectral distribution(?)
add informative footnote (e) to table 68-2 that 120m is achieved if laser BW of 400MHz.km	SuggestedRemedy
is achieved with the launch condition.	Following Derickson, use FWHP instead of RMS spectral width. Add informative note that spectrum is typically non-Gaussian.
Response Response Status C	Response Response Status C

The maximum transmitter waveform dispersion penalty (TWDP) is permitted to be 0.5 dB higher than the highest TWDP stress applied to the receiver in the comprehensive stressed receiver test. This creates a significant lack of closure in the power budget that fails to ensure link operation.	The nominal stress level of 4 dB for the simple stressed receive test that corresponds to the nominal rise and fall time of 115 ps is inconsistent with the allowed stress from the transmitter defined by the 4.7 dB maximum TWDP of line 31 on page 25.
SuggestedRemedy	SuggestedRemedy Adjust the rise and fall time to create a receiver stress level consistent with the transmitter
Increase the stressor level of all three stressor waveforms so that at least one meets or exceeds the maximum transmitter TWDP by choosing new stressors using previous	permitted stress level defined by max TWDP. If max TWDP remains at 4.7 dB, increase the rise and fall time to produce the corresponding receiver stress level.
methodology. If the transmitter TWDP remains at the present 4.7 dB, then increase the stressor level of all three by at least 0.5 dB.	Response Response Status U

### Comment Type **GR** Comment Status **R**

Although the TF passed a motion at the November meeting in Vancouver which accepted that interoperation has been demonstrated, serious deficiencies were noted in the Interoperability study. 1) The most serious is that two launches are allowed by the standard, but the results were only reported as "passing one or the other launch option." This is a serious deficiency because there were only four fibers with seven possible launch conditions in a study which needs to represent three possible fiber impulse response categories (precursor, postcursor, and split-symmetric), Apparently, however, some transmitter/receiver combinations could not equalize one or the other launch on some fibers, and this information was withheld. As a result, it is not possible to judge the true meaning of movey 1 1105. 2) Based on discussion during the October Corning meeting, it seems that other fibers were studied at the same time as the interop, but results were not reported because they "were not part of the Interop." 3) It appears to be the case that the Interop employed EDC chips from only two vendors, which would severely limits the usefulness of the study, even though the TF had originally demanded that an Interop should include PMDs from at least three vendors. This is an issue because the complexity of the EDC circuit and its ability to adapt, to a large degree, drive other design features in a transceiver. Thus employing chips from at least three vendors is a necessary condition for have three truly independent implementations of an LRM transceiver.

### SuggestedRemedy

The results of the Interop should be more fully published, including whether the center or offset launch passed in each case. Further work should be done so that at least three EDC chip vendors circuits are used in the Interop.

Response Response Status U

REJECT.

As this comment does not address the 802.3aq document, nor any IEEE SA process requirements, it is out of scope. This is the view of the 802.3 Chair.

The Task Force and the Working Group have both passed motions accepting the presented interop results.

The Task Force encourages developers to publish results, through appropriate industry channels, but the IEEE SA has no authority to require such tests, nor the publication of the results.

### Comment Type TR Comment Status R

Although the TF passed a motion at the November meeting in Vancouver which accepted that interoperation has been demonstrated, serious deficiencies were noted in the Interoperability study. Instead of launching directly into a MM patchcord, as called out in 68.4.1, the center launch was implemented in the Interop with an intervening single mode fiber patch cord between MDI and TP2. This had the likely effect of serving as a mode filter for higher order modes launched into the single mode stub in a low tolerance laser package, possibly improving the results artificially.

### SuggestedRemedy

Change the draft to mandate the use of a single mode patch cord between the transmitter and center launch, or else repeat the Interop study without the single mode fiber patch cord in the center launch implementation.

Response Response Status U

REJECT.

The Task Force and the Working Group have both passed motions accepting the presented interop results.

The use of a single mode patch cord is undesirable for CL as this would require the use of another patch cord type - having one SMF and one MMF.

The interop test was not intended to test all worst case conditions.

The SMF was used during the interop testing to connect a single mode attenuator. The attenuator was used to accommodate receivers that did not have the necessary overload performance to operate without one.

It should be noted that the document is not prescriptive about how a transmitter that meets the encircled flux spec is to be implemented. Within an implementation, use of a single mode connection is one possibility.

It should also be noted that a number of presentations have been made showing that system performance is not strongly affected, in the case of CL, by the exact launch conditions, provided that the EF spec is met. Eg: cunningham\_1\_1005.

### Comment Type TR Comment Status R

It is physically unreasonable that OM2 fiber should have the same operating range as OM3 fiber, for receivers tested against a single set of stressors, unless the TF is being very conservative on OM3 (which is not the case). OM3 fiber cannot use offset launch because the alpha shift is too large. OM3 can use center launch productively because OM3 fiber is subjected to stringent DMD testing, limiting the center defects. OM2 fiber is either fiber which was not manufactured with the strict process control required for OM3 fiber, or else it can be a downgraded product which did not meet OM3 specifications. Both these facts point to poor center launch performance compared to OM3. Thus the ~33% of OM2 fiber which is optimized at 850nm will have poor offset launch performance like OM3 due to tuning, but also much worse center launch than OM3. Therefore it is highly unlikely that the 99% tile distance for OM2 should be 220m.

### SuggestedRemedy

Either eliminate OM2 fiber from Table 68-2 or calculate an independent value for the 99% tile operating range using a Monte Carlo delay set, as was done for OM1 and OM3.

### Comment Type TR Comment Status R

Although the TF passed a motion at the November meeting in Vancouver which accepted that interoperation has been demonstrated, serious deficiencies were noted in the Interoperability study. 1) The most serious is that two launches are allowed by the standard, but the results were only reported as "passing one or the other launch option." This is a serious deficiency because there were only four fibers with seven possible launch conditions in a study which needs to represent three possible fiber impulse response categories (precursor, postcursor, and split-symmetric). Only one fiber-launch condition (40range CL) of the seven should have challenged receivers which passed the stressed sensitivity test. Apparently, however, some transmitter/receiver combinations could not equalize one or the other launch on some fibers. This is disturbing, because our methodology for both quantifying the difficulty of equalizing fibers and for implementing a stressed receiver sensitivity test trelies on the use of the PIE-D metric. The apparent failure of compliant parts to equalize all of the combinations presented in the Interop study raises serious questions about whether or not the stressed receiver sensitivity test is appropriately rigorous.

### SuggestedRemedy

In the absence of more quantitative analysis, it is recommended to adopt the "~4.5dB PIE-D Ewen stressors" that were previously advocated in London and San Francisco in comments by Bhoja, Swenson, and Telang. These were Ewen 23, 22, and 20 for pre-, quasi-symmetric, and post-cursor cases.

Response Response Status U

REJECT.

The Task Force and the Working Group have both passed motions accepting the presented interop results.

The reported PIE\_D values were means, as measured separately in the lab, and not peak values that may occur when the shaker is used.

The committee does not agree that any results presented in the interop report suggest that the receiver compliance test requires modification.

Comment Type TR Comment Status A

Starting with D2.0, some TF members have raised an issue about jitter tolerance and interoperability. In the November Vancouver TF meeting, during discussion of Ali Ghiasi's comment 11, I heard three independent observers agree with Ali that it is possible for a compliant part not to interoperate based on jitter issues that are not fully addressed by the standard. However, this issue continues to get rolled forward to the next meeting.

### SuggestedRemedy

Address the jitter and interoperability issue as recommended in ghiasi\_1\_1105 and D2.4 comment 11 (referencing 802.3ae) or equivalent approach

Response Response Status U

ACCEPT IN PRINCIPLE.
