

Comment Type TR Comment Status X

D3.0 comment 23 (formerly 88): 'The Symmetrical tap weight values would benefit from further work.' When we chose this stressor it was intended as the easiest of the three, by a small amount. Because the calculations did not include the effect of transmitter noise, while the CSRS test has significant deliberate transmitter noise, it turns out that it is the hardest of the three. As only a small proportion of relevant impulses are split, this does little for coverage and encourages people to 'build to the test' not to what's useful to the customer. Also this strong sensitivity to noise makes for calibration inaccuracy.

SuggestedRemedy

Split-symmetric candidate 1 from http://ieee802.org/3/aq/public/oct05/ewen_1_1005.pdf is a bit better behaved with transmitter noise. Or much better, remove the split-symmetric test.

Proposed Response Response Status **O**

effectively, we have assumed a factor of 1 while Gigabit and 10 Gigabit Ethernet assumed 0.7 or 0.55. Anyway, it is not feasible to make transmitters that are all at worst RIN.

SuggestedRemedv

I believe the Tx RIN spec is OK but the element of RIN in Qsg should be reduced to sqrt(0.7) or less vs. present values, for this effect.

Proposed Response Response Status **O**

Comment Type TR Comment Status X

D3.0 comment 24 (formerly 62) on RIN specification and 43 on transmitter SNR for CSRS. We choose Qsg by calculating the effect of RIN and modal noise. Our estimate of modal noise is very pessimistic. Using the Monte Carlo technique we can calculate a reasonable upper estimate of modal noise, as we can for connector loss. We see the same very skewed distribution, where the great majority of cases have negligible modal noise, and on the other hand a tiny minority would be predicted to fail through modal noise even in a nonequalised link such as 1000BASE-L or 10GBASE-S. Per comment 29 (formerly 61) 'Straw poll 1: There is margin within the link budget.'

SuggestedRemedy

Reduce the element of modal noise in Qsg.

Proposed Response Response Status O

optical amplifiers) - and not vet proven in multiple labs. Getting the noise wrong, in amount or color. can lead to significant measurement errors or even error floors (it's the noise before the transversal filter that causes trouble rather than after). Giving more information about the noise, as in p47 line 51, helps with amount but not color, and still the test is over complicated. Calibrating the noise color would require a spectrum analyzer. In short, we are not likely to get agreement between customer and supplier with such an involved test. Maybe the industry would be better served by more consistent measurements without deliberate noise loading. This would correspond better to the usual case in service, where

connector loss is small, modal noise is small, and RIN is several dB better than spec.

SuggestedRemedv

Remove the noise loading from CSRS. Don't reduce the sensitivity limits much because of this change - they are already low as compared with expected OMAs in service.

deliberate noise loading is new for an optical standard (there is something a bit like it with

Comment Status X Comment Type **TR**

D3.0 comment 34 (formerly 109): 'This test is far too complicated to be readily done by most development labs'. One item of little value is the split-symmetric stressor, because so few of the channels an equalizer would have to deal with are like this: they don't occur with OM3 and while they are reasonably common with OM1, center launch OR OM1, offset launch - with joint launch, almost every time one shows up, the other launch is better, and the equalizer doesn't have to deal with it. Further, in reality only a small fraction of split pulses would have a harmonic relation to the line rate. I expect smooth-symmetric channels would be more common, but if an equalizer can cope with our pre and post stressors, it should be OK with smooth sym of the same TWDP - we have considered adding this before and chose not to.

SuggestedRemedy

Remove the split-symmetric test.

SuggestedRemedy

Proposed Response

This is a pile-on to D3.0 comment 34.

The stress test is too complex.

In particular the noise loading is bad for a few reasons. Firstly, the noise loading has been effectively dead reckoned by the committee. A slight slip and perfectly good implementations will be ruled out. It already appears that this may be happening as I have received feedback that CMOS implementations have difficulty with the split symmetric stressor especially with noise loading. Secondly, the noise loading complicates the test for example even if its level is correct its colour must be controlled too.

Also, Ethernet conformance test should check that an implementation is reasonable they should NOT be attempting to test worst-worst case corners as the current stress test seems to have been designed to do.

The split symmetric test with noise loading is pathological in all these respects.

Removal of the split symmetric stressor and noise loading would substantially simplify the stress testing.

SuggestedRemedy

Remove the split symmetric stressor.

Remove all noise loading from the stress tests by deleting the Q specification in table 68-5 and everywhere else in the draft.

Proposed Response Response Status O

Comment ID # 31

This is a pile on comment to comment 113 to draft 3.0. In a straw poll recorded in the discussion on comment 29 to draft 3.0 it was agreed that there is margin within the link budget. (Agree 14, Disagree 1, Abstain 2). This margin should be used to reduce the cost

this value would improve the yield of LR modules and could enable SFP+ form factor

products by allowing somewhat more deterministic litter in the Tx.

Change the Max value of TWDP in table 68-3 from 4.7dB to 4.9dB.

Response Status **O**

of LRM implementations. One way to do this was suggested in comment 29. Another way which was suggested in comment 113 was to increase the TWDP value. A relaxation in
