The space as thousands separator in numbers with fractional digits is unusu confusing.	and The "(row, column)" column seems redundant with the GMP word numbers. Also, "ro only used for illustration and "column" is not defined.
Also the tilde prefix with numbers with three fractional digits seems unneces especially since these numbers are then bounded by integer values.	y, Consider deleting the third column. Otherwise, change "column" to "bit #".
SuggestedRemedy	Proposed Response Response Status W
Change "between ~10 214.684 and ~10 217.136" to "between 10 214 and 10	18". PROPOSED ACCEPT IN PRINCIPLE.
Alternatively keep the fractions and delete the space separators.	Delete the 3rd column from Table 155-1.

Comment Type T Comment Status D	Comment Type T Comment Status D					
"RRC Roll-Off" is not a unit. It is unclear what it means in this context.	"Average receive power (max)" does not depend on the receiver, but on the channel output. So it can't be a receiver specification (as the text above the table states).					
Similarly for the (min) row.						
The spectral mask is specified in 156.9.4 - reading this subclause it becomes clear that the	Maybe it should be "Average receive power tolerance (min)"?					
"Value" in the table are the beta parameter values for the two masks.	Similarly for "Average receive power (min)" which may be a tolerance requirement.					
Instead of listing numbers that are meaningless without reading the subclause text, simply point to the subclause.	Similarly for Receiver OSNR (also defined in Table 156-8 for the channel, with the same value).					
SuggestedRemedy	SuggestedRemedy					
Change "Value" to "See 156.9.4" and use em-dash for "Unit" in both rows.	Change parameter names and/or add explanations in footnotes.					
Proposed Response Response Status W PROPOSED ACCEPT IN PRINCIPLE.	Consider moving parameters to the black link characteristics in Table 156-8 or deleting duplicates.

Huber, Thom	nas	Nokia		
Comment Ty	vpe T	Comment Status D		PCS description

The two paragraphs of 155.2.4.1 jump back and forth between 66b and 257b blocks in a way that could confuse a reader who is unfamiliar with the details of the clause 119 PCS.

#### SuggestedRemedy

#### Rewrite the text as follows:

The transmit PCS generates 66-bit blocks based upon the TXD<63:0> and <TXC<7:0> signals received from the 400GMII, as specified in the transmit state diagram showni in Figure 119-14. One 400GMII data transfer is encoded into one 66-bit block. The contents of each block are contained in a vector tx\_coded<65:0>, which is passed to the 64B/66B to 256B/257B transcoder. tx\_coded<1:0> contains the sync header and the remainder of the bits contain the block payload. The rate matching described in 119.2.4.1 is not required for the 400GBASE-ZR PCS because the mapping of the transcoded block stream into the 400GBASE-ZR frame structure performs clock compensation between the two clock domains.

### Proposed Response Response Status W

PROPOSED ACCEPT IN PRINCIPLE.

Replace the text at 155.2.4.1 with:

"The transmit PCS generates 66-bit blocks based upon the TXD<63:0> and TXC<7:0> signals received from the 400GMII, as specified in the transmit state diagram shown in Figure 119-14. One 400GMII data transfer is encoded into one 66-bit block. The contents of each block are contained in a vector tx\_coded<65:0>, which is passed to the 64B/66B to 256B/257B transcoder. tx\_coded<1:0> contains the sync header and the remainder of the bits contain the block payload. The rate matching described in 119.2.4.1 is not required for the 400GBASE-ZR PCS because the mapping of the transcoded block stream into the 400GBASE-ZR frame structure performs clock compensation between the two clock domains."

C/ 155	SC 155.2.4.3	P 38	L <b>2</b>	# 204
Huber, Th	omas	Nokia		
Comment	Type <b>T</b>	Comment Status D		GMP mapper

The description of the 20-bit pad says it is inserted after the OH blocks, but the OH is a 1280 bit field (which is later described as four chunks of 320 bits that are interleaved). Since much of the text talks about 66b blocks or 257 blocks, it is probably better to refer to the OH bits rather than blocks.

#### SuggestedRemedy

Change "A 20 bit pad of all zeros is added after the OH blocks" to "A 20 bit pad of all zeros is added after the 1280 OH bits."

Subclause 45.2.1.153.1a 'Tx index ability 48 through 63 (1.804.0 through 1.804.15)' includes the text 'For 400GBASE-ZR see Table 156–4.' at the end of the subclause. Similarly, subclause 45.2.1.157a 'Rx optical frequency ability 4 register (Register 1.824)' includes the text 'For 400GBASE-ZR see Table 156–4.' at the end of the subclause. Since Tx index ability 0 through 47 and Rx index ability 0 through 47 will now also apply to 400GBASE-ZR, as well as 100GBASE-ZR, suggest that similar text be added to the end of subclauses 45.2.1.151.1 through 45.2.1.157.1.

#### SuggestedRemedy

Suggest changes to subclauses 45.2.1.151.1 through 45.2.1.157 be added to the draft. These changes should change the text at the end of these existing subclauses that reads 'For 100GBASE-ZR see Table 154–5.' to read 'For 100GBASE-ZR see Table 154–5, for 400GBASE-ZR see Table 154–5.'.

Proposed Response Response Status W

PROPOSED ACCEPT IN PRINCIPLE.

In 45.2.1.151.1, 152.1, 153.1, 155.1, 156.1, and 157.1 change the last sentence from "For 100GBASE-ZR see Table 154–5." to "For 100GBASE-ZR see Table 154–5 and for 400GBASE-ZR see Table 156–4." In 45.2.1.150.1 add a new last sentence "For 400GBASE-ZR the specific optical frequency corresponding to each channel index number is listed in Table 156–4." In 45.2.1.154.1 add a new second to last sentence "For 400GBASE-ZR the specific optical frequency corresponding to each channel index number is listed in Table 156–4." With editorial license.

Subclause 155.2.4.11 'Hamming SD-FEC encoder' says that 'The 128-bit code words are sent as 8-bit symbols to the 400GBASE-ZR PMA sublayer on the PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request inter-sublayer signals.'. Further, subclause 155.2.5.1 'Hamming SD-FEC decoder' says 'The incoming DP-16QAM symbols are digitized to an m-bit resolution by the PMA sublayer receive direction (see 155.3.3.5) and provided to the PCS receive direction by PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication inter-sublayer signals.' and that 'The Hamming SD-

FEC decoder is a soft decision decoder and so requires a higher resolution than 2 bits / 4 levels for each of the signals XI, XQ, YI, and YQ.'. Finally, Figure 155-10 '400GBASE-ZR PMA functional block diagram' says 'm is implementation dependent and is the number of bits of resolution of the DP-16QAM symbols.'

Rather than operating as n parallel asynchronous PCS lanes that carry alignment markers and lane numbers that enable the original data to be restored or n lanes to be multiplex into m lanes, it appears the 400GBASE-ZR PMA service interface between the PCS and the PMA operates as an n-bit synchronous data path, transferring a single DP-16QAM symbol during each operation. This seems to be confirmed by subclause 155.2.4.3 'GMP mapper' that says '... 400GBASE-ZR frames are not mapped to 16 PCS lanes ...'. In the case of the transmit path, the DP-16QAM symbols are encoded as 8-bit words, 2 bits representing the 4 levels for each of the in-phase and quadrature components of the X and Y polarizations. In the case of the receive path, the DP-16QAM symbols are encoded as p bits representing q levels, where p and q are implementation dependant.

This all seems to preclude the physical instantiation of the 400GBASE-ZR PMA service interface between the PCS and the PMA as a 400GAUI. This is because [1] the PMA service interface doesn't support alignment markers and lane numbers allowing multiplexing and de-multiplexing to different widths; [2] the PMA service interface width on the receive path is implementation dependant; and [3] the PMA service interface operates as a synchronous data path, transferring a single DP-16QAM symbol during each operation, requiring a skew between the bits of less than one 400GBASE-ZR frame DP-16QAM symbol time (~17.3 ps) which I don't believe a 400GAUI would meeting. This seems to be confirmed by the one example given in annexe 120A.6 'Partitioning example supporting 400GBASE-ZR' which only shows a 400GAUI 'above' the 400GBASE-ZR PCS, and not 'below'.

Based on the above, add footnotes to the 'O's in the 400GAUI columns of the 400GBASE-ZR row in Table 116–5 to note the 400GAUI is only supported 'above' the 400GBASE-ZR PCS.

#### SuggestedRemedy

Add a footnote to the 'O's in the 400GAUI columns of the 400GBASE-ZR row in Table 116–5 that reads '400GAUI only supported as a physical instantiation of the 400GMII Extender (see 118.1.3).'.

Comment Type	⇒ TR	Comment Status X		DSP frame

contents of the sub-frame 0 between P4 and P115, and sub-frame 1 and 48 between nd P115, are not defined in Figure 155-12.

ub-frame 0, the number of symbols shown in Figure 155-12 after P0, P1, P2, P3 and is 31. A sub-frame is 3712 symbols long, and there are 116 PS symbols, and since /32 = 116 it seems reasonable to assume that there are 31 symbols after every PS ol for sub-frame 0, but this needs to be specified.

ub-frame 1, the number of symbols shown in Figure 155-12 after P0 is 31, after P1 is owever, after P115 it is 32. Similarly, for sub-frame 48, the number of symbols shown ure 155-12 after P0 is 42, after P1 is 31, and after P115 it is 32. It is therefore difficult ake an assumption about the number of symbols after each PS between P2 and so this needs to be specified.

#### dRemedy

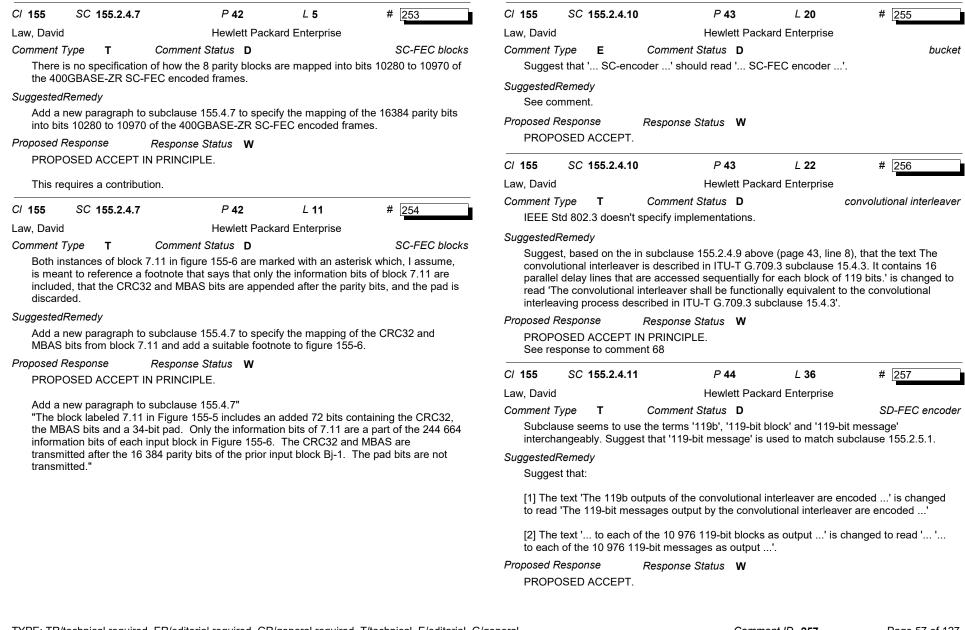

ify the contents of the sub-frame 0 between P4 and P115, and sub-frame 1 and 48 een P2 and P115.

Law, David		Hewlett	Packard Enterpri	se

Comment Type TR Comment Status D

Subclause 155.2.4.11 'Hamming SD-FEC encoder' says that 'The 128-bit code words are sent as 8-bit symbols to the 400GBASE-ZR PMA sublayer on the

PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request inter-sublayer signals.'. Further, subclause 155.2.5.1 'Hamming SD-FEC decoder' says 'The incoming DP-16QAM symbols are digitized to an m-bit resolution by the PMA sublayer receive direction (see 155.3.3.5) and provided to the PCS receive direction by PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication inter-sublayer signals.' and that 'The Hamming SD-FEC decoder is a soft decision decoder and so requires a higher resolution than 2 bits / 4 levels for each of the signals XI, XQ, YI, and YQ.'. Finally, Figure 155-10 '400GBASE-ZR PMA functional block diagram' says 'm is implementation dependent and is the number of bits of resolution of the DP-16QAM symbols.'

Rather than operating as n parallel asynchronous PCS lanes that carry alignment markers and lane numbers that enable the original data to be restored or n lanes to be multiplex into m lanes, it appears the 400GBASE-ZR PMA service interface between the PCS and the PMA operates as an n-bit synchronous data path, transferring a single DP-16QAM symbol during each operation. This seems to be confirmed by subclause 155.2.4.3 'GMP mapper' that says '... 400GBASE-ZR frames are not mapped to 16 PCS lanes ...'. In the case of the transmit path, the DP-16QAM symbols are encoded as 8-bit words, 2 bits representing the 4 levels for each of the in-phase and quadrature components of the X and Y polarizations. In the case of the receive path, the DP-16QAM symbols are encoded as p bits representing q levels, where p and q are implementation dependant.

It, therefore, doesn't seem correct to define the 400GBASE-ZR PMA service interface through reference to the lane-based PMA service interface definition in 116.3 when it doesn't support the features of a lane-based service interface. Based on this, suggest that the 400GBASE-ZR PMA service interface be defined using a single .request and .indicate primitive, with a tx\_symbol and rx\_symbol parameter respectively, to reflect the synchronous data path nature of the interface.

#### SuggestedRemedy

Specify the 400GBASE-ZR PMA as a single .request and .indicate primitive, with a tx\_symbol and rx\_symbol parameter respectively as follows:

- Change the three instances of 'PMA:IS\_UNITDATA\_i.request' to read 'PMA\_UNITDATA.request' in subclause 155.2.1 'Functions within the PCS'.

- Change subclause 155.1.4.2 'Physical Medium Attachment (PMA) service interface' to read as follows:

The 400GBASE-ZR PMA service interface provided by the 400GBASE-ZR PMA for the 400GBASE-ZR PCS is described in an abstract manner and does not imply any particular implementation. The 400GBASE-ZR PMA Service Interface supports the exchange of

encoded DP-16QAM symbols between the PCS and PMA sublayer. The 400GBASE-ZR PMA service interface is defined in 155.3.2.

- Change the last paragraph of subclause 155.2.4.11 'Hamming SD-FEC encoder' to read:

The 128-bit code words are sent as 8-bit encoded DP-16QAM symbols to the 400GBASE-ZR PMA sublayer using sixteen PMA\_UNITDATA.request messages.

- Change the text '... by PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication inter-sublayer signals.' to read '... by the PMA\_UNITDATA.indication primitive.' in subclause 155.2.5.1 'Hamming SD-FEC decoder'.

- Change subclause 155.3.2 '400GBASE-ZR PMA service interface', adding new subclauses 155.3.2.1 through 155.3.2.2.3, to read:

155.3.2 400GBASE-ZR PMA service interface

The 400GBASE-ZR PMA Service Interface supports the exchange of encoded DP-16QAM symbols between the PCS and PMA sublayer. The inter-sublayer 400GBASE-ZR PMA service interface is described in an abstract manner and does not imply any particular implementation. The inter-sublayer service interface primitives are defined as follows:

PMA\_UNITDATA.request PMA\_UNITDATA.indication PMA\_SIGNAL.indication

The PMA\_UNITDATA.request primitive is used to define the transfer of a DP-16QAM symbol from the 400GBASE-ZR PCS to the 400GBASE-ZR PMA. The PMA\_UNITDATA.indication primitive is used to define the transfer of a DP-16QAM symbol from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS. The PMA\_SIGNAL.indication primitive is used to define the transfer of signal status from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

155.3.2.1 PMA\_UNITDATA.request

This primitive defines the transfer of encoded DP-16QAM symbols in the tx\_symbol parameter from the 400GBASE-ZR PCS to the 400GBASE-ZR PMA.

155.3.2.1.1 Semantics of the primitive

PMA\_UNITDATA.request (tx\_symbol)

During transmission, the PMA\_UNITDATA.request simultaneously conveys 8 bits of a 128bit code word generated by the SD-FEC encoder (see 155.2.4.11) representing an encoded DP-16QAM symbol to the PMA. The encoding used for the in-phase and quadrature-phase components of the X and Y polarization is defined in subclause 155.3.3.1.

Comment ID 263

Page 60 of 127 9/12/2022 12:14:48 PM

TYPE: TR/technical required ER/editorial required GR/general required T/technical E/editorial G/general COMMENT STATUS: D/dispatched A/accepted R/rejected RESPONSE STATUS: O/open W/written C/closed U/unsatisfied Z/withdrawn SORT ORDER: Comment ID

#### 155.3.2.1.2 When generated

The PCS generates sixteen PMA\_UNITDATA.request messages for each 128-bit code word from the PCS SD-FEC encoder. The messages convey the least significant octet C<7:0> first, most significant octet C<127:120> last, with code word bits C<n+7:n> mapped to tx\_symbol<7:0>. The nominal rate of PMA\_UNITDATA.indication messages is 57.78 GBd.

#### 155.3.2.1.3 Effect of receipt

The PMA continuously forms the tx\_symbol parameters received in sixteen consecutive PMA\_UNITDATA.indication messages into 128-bit code words that are passed to the PMA Gray mapping and polarization distribution function (see 155.3.3.1).

#### 155.3.2.2 PMA\_UNITDATA.indication

This primitive defines the transfer of encoded DP-16QAM symbols in the rx\_symbol parameter from the 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

155.3.2.2.1 Semantics of the primitive

#### PMA\_UNITDATA.indication (rx\_symbol)

During reception, the PMA\_UNITDATA.indication simultaneously conveys m bits of an nbit code word generated by the symbol de-interleaving function (see 155.3.3.8) representing an encoded DP-16QAM symbol to the 400GBASE-ZR PCS where m is implementation dependent, representing the number of bits of the encoded DP-16QAM symbol, and n = 16 x m.

#### 155.3.2.2.2 When generated

The PMA generates sixteen PMA\_UNITDATA.indication messages for each n-bit code word generated by the PMA symbol de-interleaving function. The messages convey the least significant m bits of the n-bit code word first. The nominal rate of PMA\_UNITDATA.indication messages is 57.78 GBd.

#### 155.3.2.2.3 Effect of receipt

The PCS continuously forms the rx\_symbol parameters received in sixteen consecutive PMA\_UNITDATA.indication messages into n-bit code words that are passed to the PCS Hamming SD-FEC decoder function (see 155.2.5.1).

#### 155.3.2.3 PMA\_SIGNAL.indication

This primitive defines the transfer of the status of the PMA receive process in the SIGNAL OK parameter from 400GBASE-ZR PMA to the 400GBASE-ZR PCS.

#### 155.3.2.3.2 When generated

The PMA generates a PMA\_SIGNAL.indication message whenever there is change in the value of the SIGNAL\_OK parameter (see 155.3.3.9).

155.3.2.2.3 Effect of receipt

The PCS Synchronization process monitors the PMA\_SIGNAL.indication primitive for a change in the SIGNAL\_OK parameter (see 155.2.1).

- Move the last paragraph of the current subclause to a new subclause 155.3.3.9 titled 'Signal Indication Logic (SIL)'.

- Change the last paragraph of subclause 155.3.3.8 'Polarization combining and symbol deinterleaving' to read:

The sixteen encoded DP-16QAM symbols are transferred to the 400GBASE-ZR PCS sublayer as m-bit DP-16QAM symbols using sixteen PMA\_UNITDATA.indication messages.

- Change 'PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request' to read 'PMA\_UNITDATA.request' and 'PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication' to read ' PMA\_UNITDATA.indication' in Figure 155-2 'Functional block diagram'.

- Change 'PMA:IS\_UNITDATA\_0.request to PMA:IS\_UNITDATA\_7.request' to read 'PMA\_UNITDATA.request' and 'PMA:IS\_UNITDATA\_0.indication to PMA:IS\_UNITDATA\_m-1.indication' to read ' PMA\_UNITDATA.indication' in Figure 155-10 '400GBASE-ZR PMA functional block diagram'.

Comment Type T Comment Status D state variables The description of the 'reset' variable says that it is 'A boolean variable that controls the

resetting of the PCS and PMA sublayers' and that 'It is true whenever a reset is necessary including when reset is initiated from the MDIO ... and when the MDIO has put the PCS and PMA sublayers into low-power mode.'.

The PMA and PCS are separate MMDs (see Table 45-1). The PMA/PMD reset bit is 1.0.15 and the low power bit is 1.0.11, both found in PMA/PMD control 1 register. The PCS reset bit is 3.0.15 and the low power bit is 3.0.11, both found in the PCS control 1 register. Since these registers are in separate MMDs, and since their state is not communicate across the PMA service interface, the PMA and PCS resets can operate independently.

#### SuggestedRemedy

[1] Rename the 'reset' variable used in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to be 'pma\_reset'.

[2] Rename the 'reset' variable used in Figure 155-15 'PMA deskew state diagram' to be 'pma\_reset'.

[3] Rename the 'reset' variable used in Figure 155-16 'Alignment marker lock state diagram' to be 'pcs\_reset'.

[4] Rename the 'reset' variable defined in subclause 155.4.2.1 'Variables' to be 'pma\_reset' and change the description to read 'A Boolean variable that controls the resetting of the PMA sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PMA sublayer into low-power mode.

[5] Add a definition of the 'pcs\_reset' variable to subclause 155.4.2.1 'Variables' with the description 'A Boolean variable that controls the resetting of the PCS sublayer. It is true whenever a reset is necessary including when reset is initiated from the MDIO, during power on, and when the MDIO has put the PCS sublayer into low-power mode.

Proposed Response Response Status W

PROPOSED ACCEPT IN PRINCIPLE.

Review supporting presentation. For comment resolution group (CRG) consideration.

Comment Type	т	Comment Status	x	state variables
The description	on of the	'signal_ok' variable sa	ays 'A boolean variable that is se	t based on the

state variables

Comment Type T Comment Status X

Subclause 155.4.2.1 'Variables' says 'The PMA:IS\_SIGNAL.indication primitive is generated through a signal indication logic (SIL) that reports signal health based on ... symbols being sent to the PCS on all of the output lanes.'. The SIGNAL\_OK parameter of the PMA:IS\_SIGNAL.indication primitive is, however, used to derive the signal\_ok variable (page 60, line 45) which is used as an 'open arrow' entry condition to the 'LOCK\_INIT' state of the Figure 155-14 Frame alignment word (FAW) lock state diagram.

As a result, it appears that if the SIGNAL\_OK parameter is ever set to FAIL, setting 'signal\_ok' to FALSE, the figure 155-14 Frame alignment word (FAW) lock state diagram will enter the 'LOCK\_INIT' state. I assume this will mean that symbols will not be sent to the PCS since the PMA will not have FAW alignment. This in turn will mean the condition 'symbols being sent to the PCS' for the SIL to set the SIGNAL\_OK parameter to OK will not be met.

The PMA will then be locked in this condition permanently. The SIL cannot set the SIGNAL\_OK parameter to OK until symbols are sent to the PCS. Yet symbols won't be sent to the PCS until the SIGNAL\_OK parameter is set to OK.

#### SuggestedRemedy

Please clarify the operation of the signal indication logic. Suggest, based on Figure 155-10, and the dotted line from the 'Carrier phase recovery block to the SIL, that the 'signal\_ok' variable used by the Frame alignment word (FAW) lock state diagram should be based on the status of the blocks below the 'Pilot removal' blocks while the SIGNAL\_OK parameter sent to the PCS should also use the FAW alignment status.

See also my other comment suggest separate 'pma\_signal\_ok' and 'pcs\_signal\_ok' variables.

Proposed Response Response Status O

Comment Type **T** Comment Status **X** state variables The description of the 'restart\_lock' variable says 'A boolean variable that is set by the frame alignment word (FAW) lock process to reset the synchronization process on all PMA lange. It is get to TPUE when 15 FAWs in a row fail to match (15 BAD state) ' While the

frame alignment word (FAW) lock process to reset the synchronization process on all PMA lanes. It is set to TRUE when 15 FAWs in a row fail to match (15\_BAD state).'. While the restart\_lock variable is used in the frame alignment word (FAW) lock process described in Figure 155-14, it is also used in the Alignment marker lock process described in Figure 155-16.

### SuggestedRemedy

[1] Rename all instances of the 'restart\_lock' variable used in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to be 'pma\_restart\_lock'.

[2] Rename all instances of the 'restart\_lock' variable used in Figure 155-16 'Alignment marker lock state diagram' to be 'pcs\_restart\_lock'.

[3] Rename 'restart\_lock' variable in subclause 155.4.2.1 'Variables' to be 'pma\_restart\_lock'.

[4] Add a definition of the 'pcs\_restart\_lock' variable to subclause 155.4.2.1 'Variables'.

The description of the 'faw\_valid' variable says 'The FAW consists of one of the sequences listed in Table 155-3.' but then 'The sequence is considered to be valid if at least 36 bits match the 44 known bits of the FAW pattern described in 155.3.3.3.1.'. The sequence listed in Table 155-3, and the candidate sequences received over the PMD service interface, are both 22 DP-16QAM symbols, not 44 bits. Based on slide 4 of the contribution 'faw valid analysis' from Mike Sluyski

<https://www.ieee802.org/3/cw/public/22\_0523/sluyski\_3cw\_01a\_220523.pdf#page=4> referencing a 'QPSK FAW' value of 44 in the spreadsheet, I assume the reference to 36 bits matching the 44 known bits should be to 36 16QAM symbols matching the 44 16QAM symbols (which form the 22 DP-16QAM symbol FAW sequence), defined in Table 155-3.

Additionally, isn't it the case that the four components of the DP-16QAM symbols of the candidate 22 symbol block received over the four-lane PMD service interface can be mapped to the four lanes in any of eight ways defined in Table 155-7? If that is the case, suggest that this is also addressed in the description of the 'faw\_valid' variable.

#### SuggestedRemedy

Suggest that the 'faw\_valid' variable description should be changed to read:

A Boolean variable that is set to true if the candidate 22 DP-16QAM symbol block received over the four-lane PMD service interface is a valid FAW sequence. The candidate 22 DP-16QAM symbol block is compared to the FAW sequence defined in Table 155-3, considering all permitted PMD service interface lanes mappings defined in Table 155-7. The candidate 22 DP-16QAM symbol block is considered to be a valid FAW sequence if at least 36 of its component 16QAM symbols match, in value, sequence position, and the 44 known 16QAM symbols of the FAW sequence defined in Table 155-3.

Proposed Response Response Status **O** 

The definition of the 'faw\_valid' variable says '... set to true if the received 22-symbol block is a valid FAW.'. According to the super-frame format defined in subclause 155.3.3.3 the 22 FAW symbols are transmitted over a total of 23 symbols, as Pilot Sequence index P1 is inserted between the symbols faw<20> and faw <21> (see figure 155-12). As a result, a valid FAW will never be found in a received 22-symbol block, only in a received 23-symbol block after the 22nd symbol is deleted.

#### SuggestedRemedy

If needed, clarify the definition of the 'faw\_valid' variable to account for the P1 symbol inserted between the faw<20> and faw <21> symbols.

Proposed Response Response Status **O** 

C/ 155	SC 155.4.2.1	P 61	L 18	# <u>2</u> 89
Law, David		Hewlett Pack	ard Enterprise	
Comment Ty	pe T	Comment Status X		state variables
0				

Subclause 155.3.3.3 'Insert FAW, TS and PS symbols' says that 'A super-frame is defined as .... including 175 616 payload symbols and 6272 additional symbols.' and that 'The first sub-frame of a super-frame includes ... a 22-symbol FAW (faw<0:21>) ... and 3488 payload symbols (m<0:3487>).'. Based on this it seems that the FAW is not considered part of the payload.

### SuggestedRemedy

Since the title of subclause 155.3.3.3.1 'Frame alignment word (FAW) sequence', suggest that the four instances of '... FAW payload ...' (page 61, lines 16, 18, 20 and 23) be changed to read '... FAW sequence ...'.

Comment Status 🗙

The description of the variable 'current\_pmal' says 'The PMA lane number is determined by the FAW payloads based on the mapping defined in 155.3.3.3.1.' and the description of the variable 'pma\_lane' says 'The PMA lane number is determined by matching the received 22-symbol sequence to the values in one of the columns of Table 155-3 ...'. Subclause 155.3.3.3.1, nor Table 155-3, provide any lane numbers.

The PMA lane number is not referenced outside the state diagrams, other than in Table 155-9 where pma\_lane\_mapping<x> is mapped to register 3.400 through 3.403, which doesn't seem correct as these are PCS lane registers, not PMA lane registers (see my other comment on this). As a result, rather than add PMA lane numbers to subclause 155.3.3.1 and/or Table 155-3, suggest references to 'PMA lane numbers' be changed to 'PMA lane identifiers' with the values 'Ix', 'Qx', 'Iy' and 'Qy'. The state diagram can compare PMA lane identifiers to see if they match and can test for a unique PMA lane identifier for each PMA lane as easily as it can for PMA lane numbers.

In addition, the description of the 'faw\_valid' variable says 'The sequence is considered to be valid if at least 36 bits match the 44 known bits of the FAW pattern described in 155.3.3.3.1.'. The description of the variable 'current\_pmal' however says 'The PMA lane number is determined by the FAW payloads based on the mapping defined in 155.3.3.3.1.'. Similarly, the description of the variable 'pma\_lane' says 'The PMA lane number is determined by matching the received 22-symbol sequence to the values in one of the columns of Table 155-3...'. Neither mention the '36 out 44' approach used for the 'faw\_valid' variable.

The 'current\_pmal' description could imply a requirement for a full match to a column of Table 155-3, and the 'pma\_lane' description requires a full match to a column of Table 155-3. Since the entry into states where 'current\_pmal' is used is based on faw\_valid = TRUE, doesn't this mean that the use of the '36 out 44' approach, which permits 8 16QAM symbols to not match, needs to be considered when determining 'current\_pmal' and 'pma\_lane'. As a worst-case example, couldn't a faw\_valid = TRUE result from eight 16QAM symbols not matching due to errors on just one phase of just one of polarization. This would seem to imply that the compare for the values received on a lane with the columns of Table 155-3 also needs to permit eight values not matching.

In the case of 'current\_pmal' and 'pma\_lane', as there are only 22 values in a column of Table 155-3, it would seem a match would have to be valid if at least 14 values received on the lane match the 22 known values defined in a column to address the worst-case of all eight errors on one phase of one of polarization. It seems there may, however, be another approach to determine 'current\_pmal' and 'pma\_lane'. Doesn't the PMD lane mapping row selected from Table 155-7 to achieve faw\_valid = TRUE inherently provide the 'current pmal' and 'pma\_lane' comment on faw valid)?

Finally, as this variable is used by a state diagram within the PMA, which sits above the PMD, the text '... is recognized on a given lane of the PMA service interface.' should read '... is recognized on a given lane of the PMD service interface.'.

SuggestedRemedy

[1] Change the description of the first\_pmal variable to read as follows (note my other comment to change the coherent signal labels in Table 155-7 would impact this item if accepted):

A variable that holds the PMA lane identifier corresponding to the first FAW sequence that is recognized on a given lane of the PMD service interface. It is compared to the PMA lane identifier corresponding to the next FAW payload that is tested. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw\_valid variable.

#### Values:

Ix: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is XI.

Qx: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is XQ.

ly: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is YI.

Qy: Value for given lane from mapping used in Table 155-7 to find the current FAW sequence is YQ.

[2] Change the description of the current\_pmal variable to read as follows:

A variable that holds the PMA lane identifier corresponding to the current FAW sequence that is recognized on a given lane of the PMD service interface. It is compared to the variable first\_pmal to confirm that the location of the FAW sequence has been detected. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw valid variable.

Values: See first pmal.

[3] Change the description of the pma\_lane variable to read as follows:

#### pma\_lane

A variable that holds the PMA lane identifier received on lane x of the PMA service interface when faws\_lock<x> = TRUE. The PMA lane identifier is determined by matching the received 22-symbol FAW sequence to the values in one of the columns of Table 155-3. The PMA lane identifier is the value for the given lane in the row of Table 155-7 that defines the PMD service interface lane mapping used to find the match for the current FAW sequence as described in the faw valid variable.

Values:

There are nine instances of 'super-frame' and two instances of 'DSP super-frame'. Suggest that one term is used consistently.

#### SuggestedRemedy

Suggest that the two instances of '... DSP super-frame ...' (page 61, line 33 and page 63) and line 4) be changed to read '... super-frame ...'.

Proposed Response Response Status 0

#### Comment Type TR Comment Status X

The description of the 'FAW COMPARE' function in subclause 155.4.2.2 'Functions' says that 'If current pmal and first pmal both found a match and ... faw match is set to true.'. Since faw valid '... is considered to be valid if at least 36 bits match the 44 known bits of the FAW pattern ...'. I assume rather than a 'match', this really should say something along the lines of 'if at least 36 symbols of the current receive 22-symbol block match the 44 known bits of the FAW pattern'.

It however seems simpler to just add faw valid is TRUE as a condition to enter the COMP state, which would become 'faw counter done \* faw valid', and have a path from the 'COUNT 2' state to the 'INVALID FAW' state if 'faw counter done \* !faw valid' is FALSE. This would also mirror the similar use of the 'FAW COMPARE' function in the 'COMP 2ND' state where the condition to transition to the state is 'faw counter done \* faw valid' and 'faw counter done \* !faw valid' results in a transition to the 'FAW SLIP' state.

#### SuggestedRemedy

[1] Change the text 'If current pmal and first pmal both found a match and indicate the same PMA lane number. faw match is set to true' in the description of the FAW COMPARE function to read 'If current pmal and first pmal indicate the same PMA lane number, faw match is set to true'.

[2] Change the condition on the transition from the 'COUNT 2' state to the 'COMP' state in Figure 155-14 'Frame alignment word (FAW) lock state diagram' to read 'faw counter done \* faw valid'.

[3] Add a transition from the 'COUNT 2' state to the 'INVALID FAW' state in Figure 155-14 'Frame alignment word (FAW) lock state diagram' that reads 'faw counter done \* !faw valid'.

The 'slip done' variable assigned to FALSE in the GET BLOCK state of the Frame alignment word (FAW) lock state diagram is not defined. Suspect it should read 'faw slip done' so that it is set to FALSE before the FAW SLIP function, which sets it TRUE, is called in the FAW SLIP state.

#### SuggestedRemedy

Change the text 'slip done <= FALSE' in the GET BLOCK state in Figure 155-14 to read 'faw slip done <= FALSE'.

SuggestedRemedy

Suggested changes:

[1] Delete the antepenultimate row of Table 155-9.

[2] Add a new subclause 155.5.1 as follows:

155.5.1 PCS lane alignment registers

The PCS lane alignment registers (registers 3.52 and 3.53) are not used as the 400GBASE-ZR PCS does not use PCS lanes across the PMA service interface (see 155.2.4.3). A 400GBASE-ZR PCS shall return a zero for all bits in these registers.

[3] Change the variable 'pma\_align\_status' in the 'ZR-PCS/PMA variable' column of the penultimate row of Table 155-9 to 'amps\_lock'.

[4] Delete the last row of Table 155-9.

[5] Add a new subclause 155.5.2 as follows:

155.5.2 PCS lane mapping registers

The PCS lane mapping registers (registers 3.400 through 3.419) are not used as the 400GBASE-ZR PCS does not use PCS lanes across the PMA service interface.

## Comment Type T Comment Status D

Subclause '155.3.3 Functions within the PMA' says that 'The purpose of the PMA is to adapt between the PCS layer digital symbols to and from the four analog signals ...' and subclause 155.3.3.4 '16QAM encode and signal drivers' says that '... stream of symbols is converted to four analog signals ...' and that 'The analog signals are sent to the 400GBASE-ZR PMD sublayer over the PMD:IS\_UNITDATA\_0.request to PMD:IS\_UNITDATA\_3.request sublayer signals.'. It, therefore, appears that the PMD service interface is a set of analogue signals. Finally, Figure 155-10 shows a DEC block above the PMD service interface.

Subclause 156.2 'Physical Medium Dependent (PMD) service interface', however, says ' In the transmit direction, the PMA continuously sends four analog streams to the PMD ... with binary values of 3, 1, -1, and -3 using the PMD:IS\_UNITDATA\_i.request primitive.'. Is it correct to say '... with binary values ...'.

## SuggestedRemedy

[1] Suggest that in subclause 156.2 (page 75, line 14) the text '... X and Y polarizations with binary values of 3, 1, -1, and -3 using the ...' should be changed to read '... X and Y polarizations with the values of 3, 1, -1, and -3 using the ...'.

[2] Suggest that in subclause 156.5.2 (page 77, line 39) the text '... X and Y polarizations with binary values of 3, 1, -1, and -3.' should be changed to read '... X and Y polarizations with the values of 3, 1, -1, and -3.'.

Comment Type	TR	Comment Status	D	
Subclause 1	56.3.2 'Skew	constraints' says	at 'The	Skew (relative delay) between the
lanes is ken	t within limits	so that the informa	tion on th	he FEC lanes can be reassembled by

lanes is kept within limits so that the information on the FEC lanes can be reassembled by the FEC.'. On review of Clause 155, 400GBASE-ZR doesn't seem to mention FEC lanes anywhere else. Further, subclause 155.2.4.3 'GMP mapper' says '... 400GBASE-ZR frames are not mapped to 16 PCS lanes ...'. As far as I can see, the 8-bit PMA service interface carries an 8-bit word that describes an DP-16QAM symbols based on the mapping defined in Table 155-2. As a result, the only lanes seem to be the PMD service interface which has four lanes which carry four analogue streams representing the in-phase and quadrature-phase component of the two polarizations (page 75, line 13).

Table 156-6 specifies a maximum polarization skew of 5 ps (page 82, line 45) and a maximum quadrature skew is 0.75 ps (page 83, line 6). Subclause 156.3.2, however, says The Skew at SP3 (the transmitter MDI) shall be less than 54 ns and the Skew Variation at SP3 is limited to 600 ps'. I suspect that the former values are correct. And based on this, assuming no retiming in the PMD, the other values in subclause 156.3.2 don't seem correct either.

# SuggestedRemedy

Since 400GBASE-ZR doesn't seem to support FEC lanes, and says it doesn't support PCS lanes, suggest that subclause 156.3.2 is deleted.

Zimmerman, 0	George	CME C	onsulting/APL Group,	Cisco, Commscope, Ma
Comment Typ	e TR	Comment Status	X	PMA description

"The signals are sampled by an ADC on each lane at a sampling rate." "The details of the ADC . are implementation specific". This is a description of an implementation, not appropriate for an interoperability specification. If someone could do the signal processing optically, analog, or by magic, it would still comply with the standard. The fact that an ADC is used, isn't a part of the interoperability standard, or even any of the characteristics of the ADC. Hence the mention is inappropriate and should be deleted. The sentence works just fine anyways and describes the processing without the "by an ADC".

## SuggestedRemedy

Change header of 155.3.5 to Receive signal sampling. On line 50, Delete "by an ADC" Change line 54 to "The details of the sampling, including any quantization and the chosen sampling rate are implementation specific." Replace "ADC" with "Sampler" in figure 155-10.

Proposed Response Response Status O

PMA block diagram

# 345

This figure is supposed to be a functional block diagram, not an implementation diagram. There are no characteristics for the DAC blocks defined in the specification. The closest thing in the text is 155.3.3.4 which are called the 16QAM encode and signal drivers. However, most other 802.3 PHY clauses leave out signal drivers, DACs and the like, and there are no specific requirements in 155.3.3.4. so deleting the blocks seems the right approach to making a functional block diagram.

## SugaestedRemedv

Preferably, delete the "DAC" blocks from Figure 155-10 (going straight to the output is fine) Alternatively, Relabel "16QAM Encoder and Signal Driver" (probably drawing as 2 blocks since you show I&Q paths)

Proposed Response Response Status 0

C/ 155	SC 155.7.4.1	P 7	0 L 24	# 346
Zimmerman,	George	CME	Consulting/APL G	roup, Cisco, Commscope, Ma
Comment Ty	pe TR	Comment Status	Х	PICS

This is a general comment on the requirements. I am attaching it to these PICS because this is where it became apparent. The style of IEEE SA standards (and IEEE Std 802.3) is that requirements use the term "shall". Each PICS item should have an associated "shall" and each "shall" should have a PICS. However, 155.7.4.1 is a list of the subclauses for the most part. Further, looking at the subclauses, they are largely without "shalls". Most of the items in clause 155 are descriptive of an implementation, and do not use the term shall. They use "is" or other descriptive language. The PICS are a list of the functional blocks described, but most of those functional blocks are lacking actual requirements. Instead they often describe an implementation or, worse yet, sometimes try to require a particular implementation ("an implementation shall"). What needs to happen is that the clause needs to be rewritten carefully considering what requirements are needed for interoperability, and deleting the unnecessary implementation description. This is a big job, and, in my opinion, means the draft is not technically complete, and should not have begun initial working group ballot. I truly regret having to make a comment like this, but I believe this is a great example of why we have working group ballots in 802.

## SugaestedRemedv

Unfortunately, the draft is so far from complete that I cannot propose a specific remedy for the systematic problem. I can suggest that the TF look at each subblock, determine what the observed behavior is, determine which parts matter to interoperability, and write "shall" statements in the subclauses. Then those shall statements can be made as PICS. Additionally, this will highlight where there is implementation description that can be deleted. When this is done, restart working group ballot.

#### Comment Type T Comment Status A

The term 400GBASE-Z seems to only once in the specification, and there is no description of the "family" described in this definition. Further, based on where it is used appears to be in error. I only find it in connection with Figure 155-2 (page 35) in the sentence "A functional block diagram of the 400GBASE-Z PCS sublayer is shown in Figure 155-2". The figure itself calls this the 400GBASE-ZR PCS, and 400GBASE-ZR is used everywhere else. Suggest this definition may be left over from some earlier thought...

## SugaestedRemedv

Delete 1.4.144b definition. Alternatively, add text to the draft (likely 155) explaining the general family and its members...

A bad CW can be detected either by detecting errors after FEC decoding or by CRC errors. This should be clarified in the counter definition.

#### SuggestedRemedy

Add the following to the definition of cw bad: An uncorrected codeword is detected if either errors remain after FEC correction or if the CRC32 check fails
