

BER budget allocation for AUIs

Adee Ran, Cisco

Introduction

- Various options of BER allocation for AUIs have been laid out in [brown 3dj elec 01a 230406](#) with simple additive budgeting.
- Latency has been analyzed in [brown 3dj optx 01b 230413](#)
- The effect of correlated errors in the AUI has been addressed in [he 3dj optx 01a 230413](#) focusing on RS codeword interleaving.
- This contribution:
 - Presents results with 2/4 RS codeword interleaving (independent analysis)
 - Compares various AUI BER allocations and levels of error correlation.

What is included

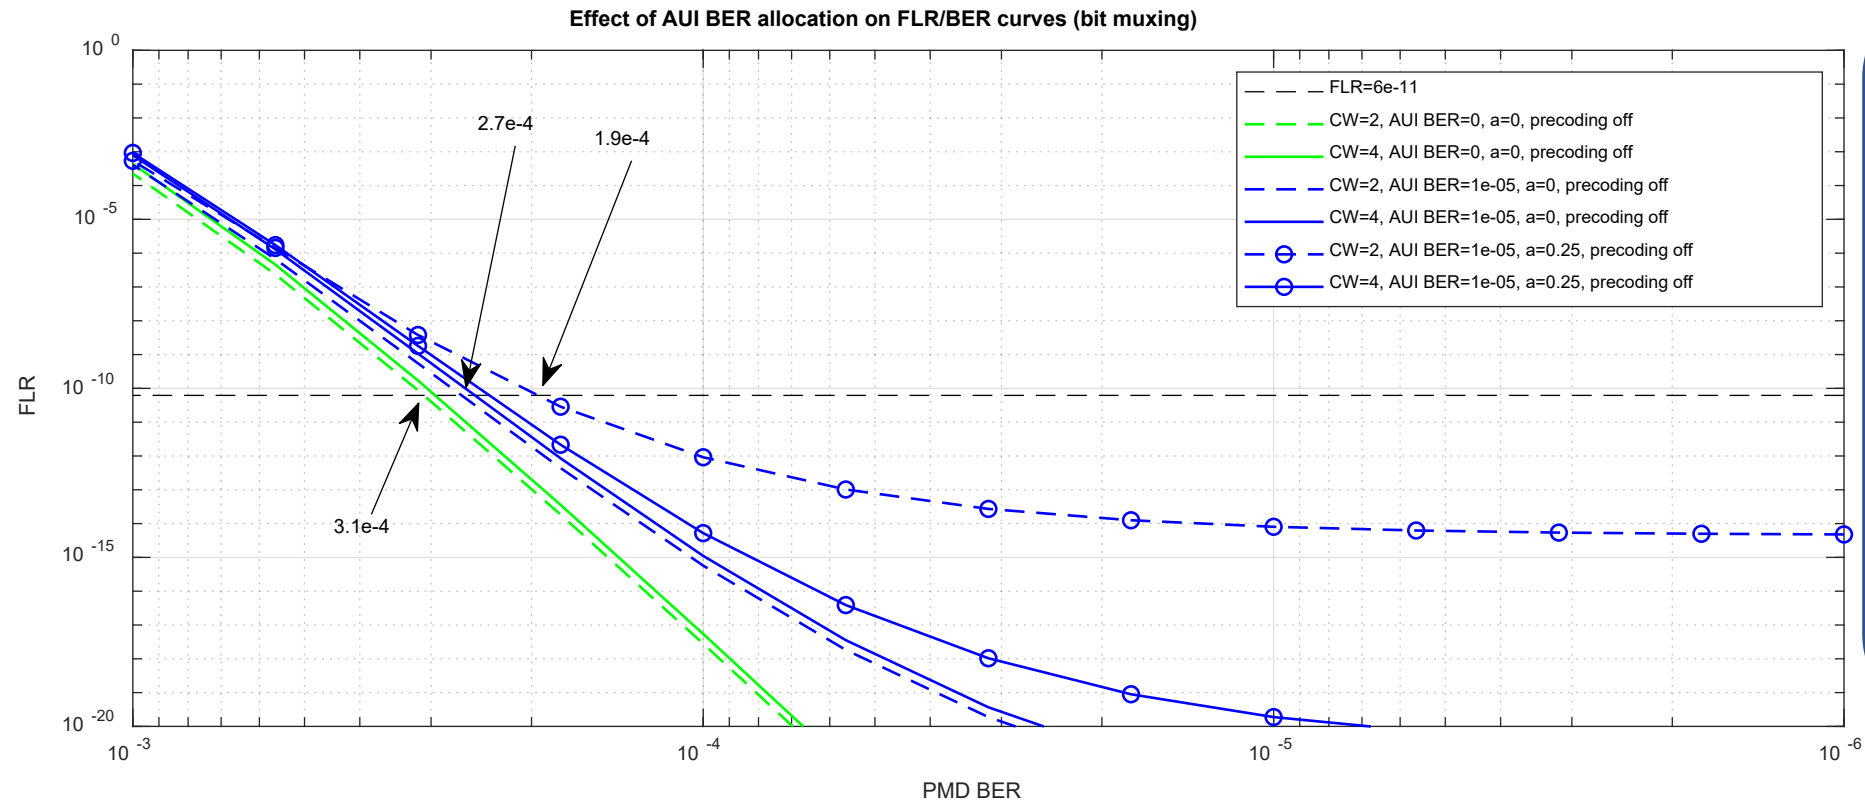

- Pure statistical analysis
- Non-segmented RS-FEC
- “PMD BER” includes a possible inner FEC decoder effect
 - This is the BER at the module output
- Number of RS codewords: 2 or 4
- 4 AUIs (2 on each side) with sweep of
 - AUI BER (before any error propagation): 0, 1e-5, 2.5e-5, 5e-5 on each (0, 2e-5, 5e-5, 1e-4 per PHY)
 - Error propagation factor a : 0, 0.25 (mild, e.g. MLSE), 0.75 (severe, e.g. strong DFE)
 - Precoding on or off (only with $a=0.75$)
- Bit muxing for 100G/lane; Symbol muxing for 200G/lane

Error correlation

- “AUI BER” is used in this presentation as **the rate of random errors** (essentially DER/2)
 - Correlation due to error propagation is a swept parameter
 - In COM analysis, the DER should be twice of AUI BER (2e-5, 5e-5, or 1e-4 per segment)
- “PMD BER” is after inner FEC decoding (if used) and is assumed to be uncorrelated.
 - The convolutional interleaver is assumed to spread each 120-bit block (which can contain several errors) across 12 different RS-FEC codewords.
 - The case of no convolutional interleaving (where up to 3 or 6 symbols of a single RS-FEC codeword can be affected) is not covered – planned as a future contribution.
 - Correlated errors/noise on the optics can affect the PMD BER but have no other effect in this analysis.

Results

Sanity check: AUI budget allocation with bit muxing (100 Gb/s)

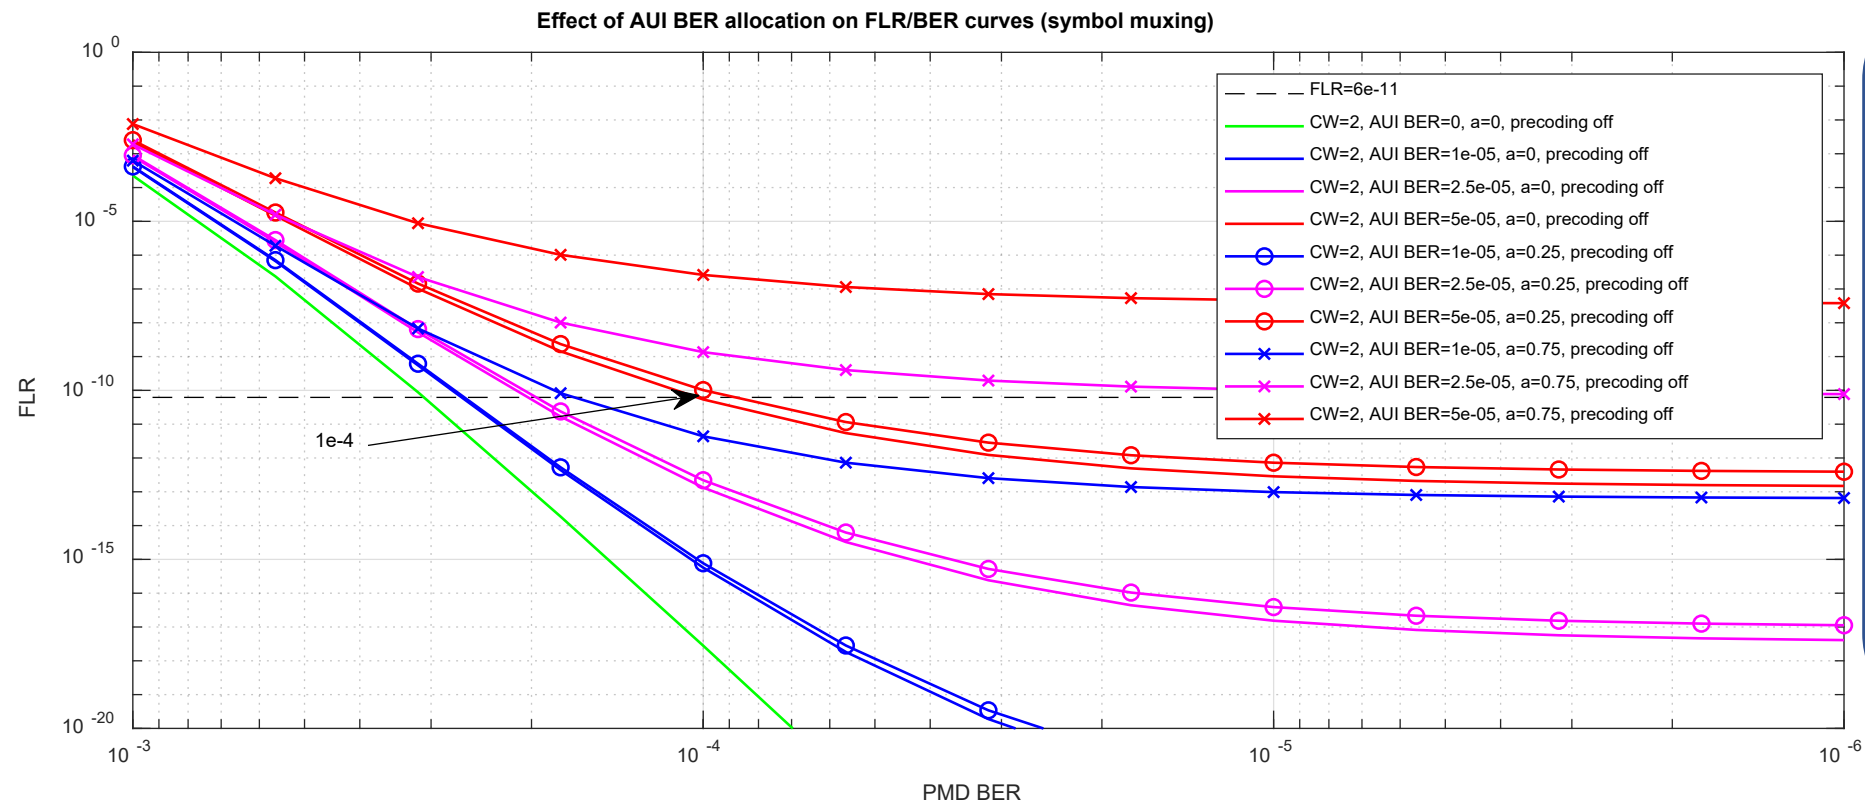

PMD BER for FLR=6.2e-11 is:

- $\sim 3.1e-4$ if AUI BER is taken as 0
- $\sim 2.7e-4$ if AUIs are allocated $1e-5$ with no error correlation

With 2-CW interleaving, even mild error correlation (corresponding to a limited DFE in AUI-C2M) has a significant FLR floor effect.

With 4 codewords the effect is smaller.

AUI budget allocation with symbol muxing (200 Gb/s), 2 CW interleaving on AUIs

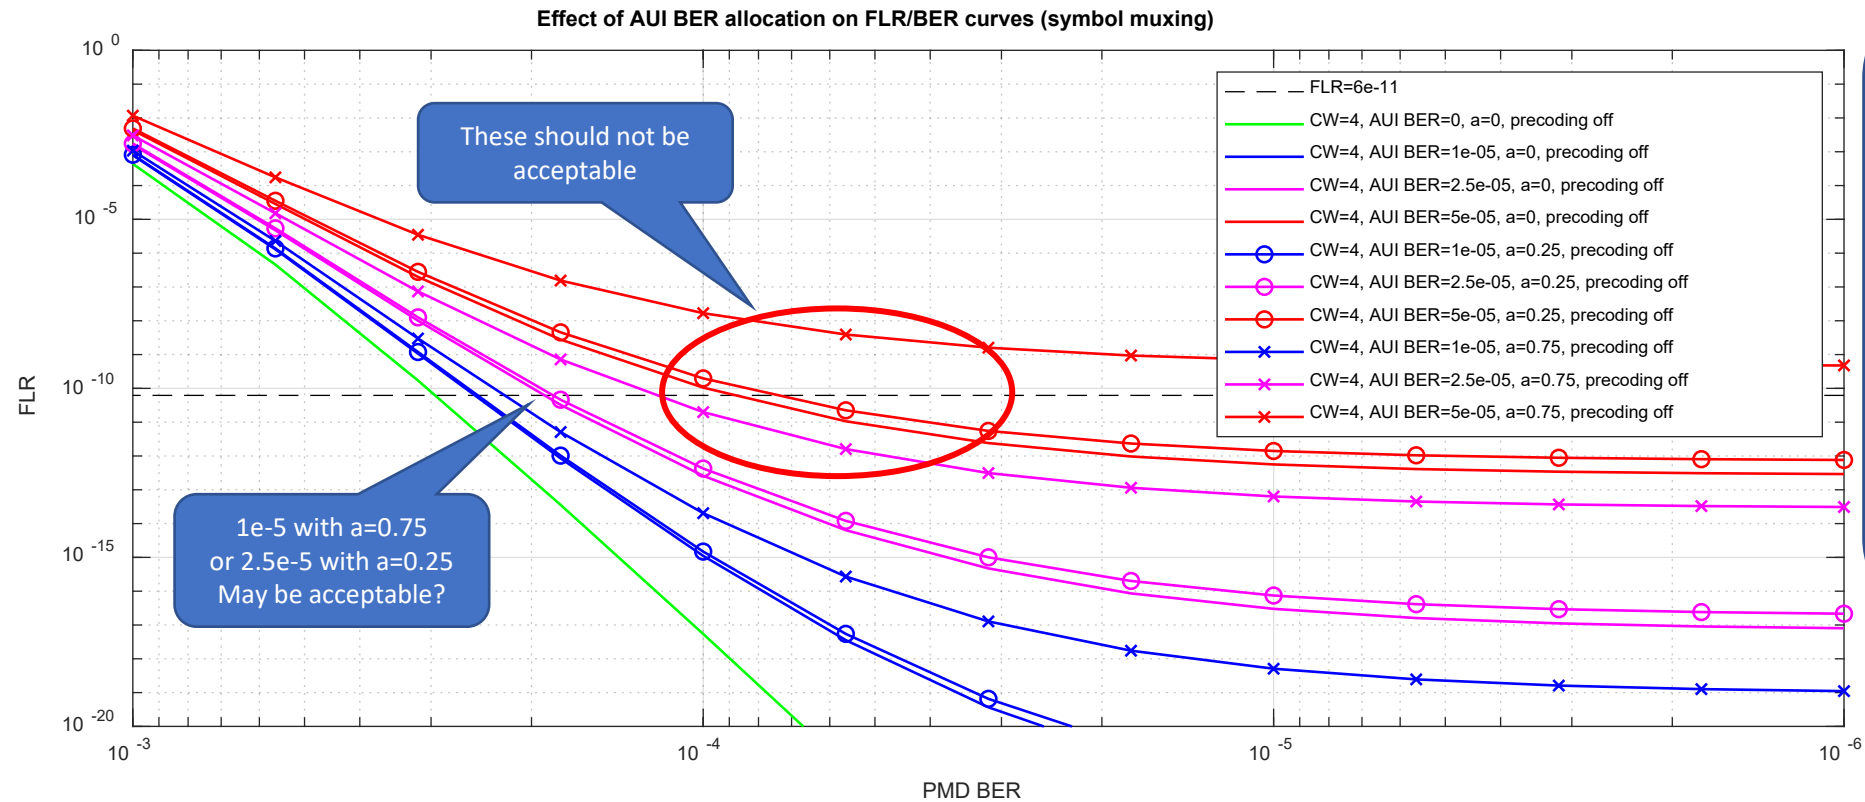

PMD BER for FLR=6.2e-11 is:

- Same as bitwise muxing under “sanity check” conditions
- $\sim 1e-4$ if AUIs are allocated 5e-5 with no error correlation
- Mild error correlation (a=0.25) creates a small increase

High “FLR floor” seen if AUI BER=5e-5 and/or a=0.75

AUI budget allocation with symbol muxing (200 Gb/s), 4 CW interleaving on AUIs

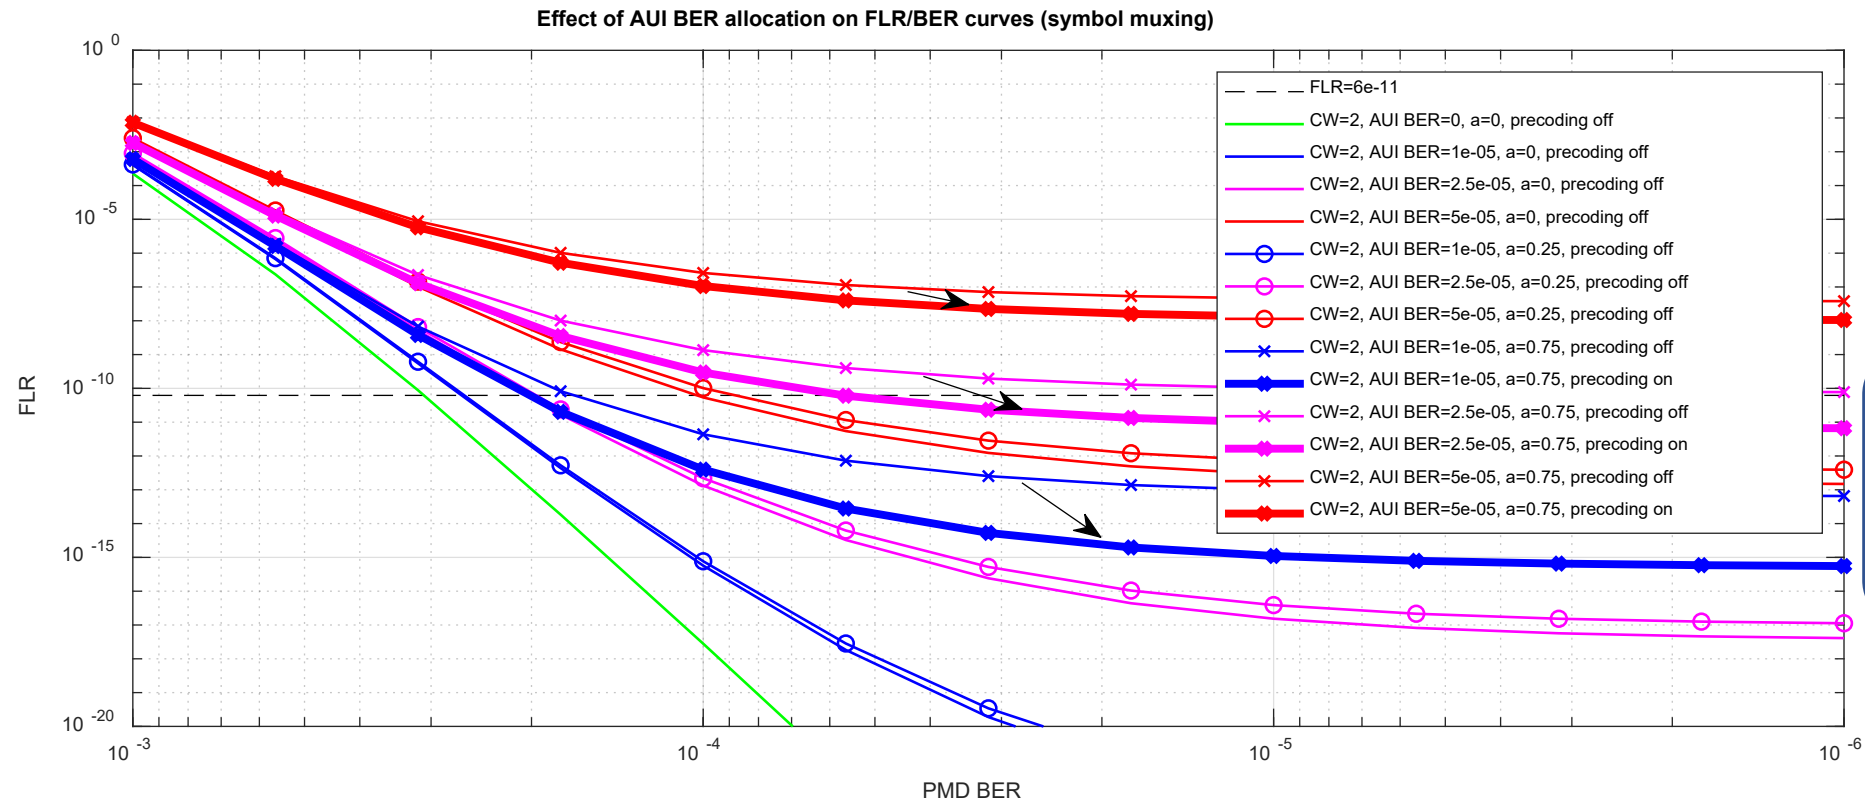

The PMD BER for FLR=6.2e-11 is:

- Same as bitwise muxing under “sanity check” conditions
- Similar to 2-CW with no error correlation
- Better (higher) than 2-CW with error correlation

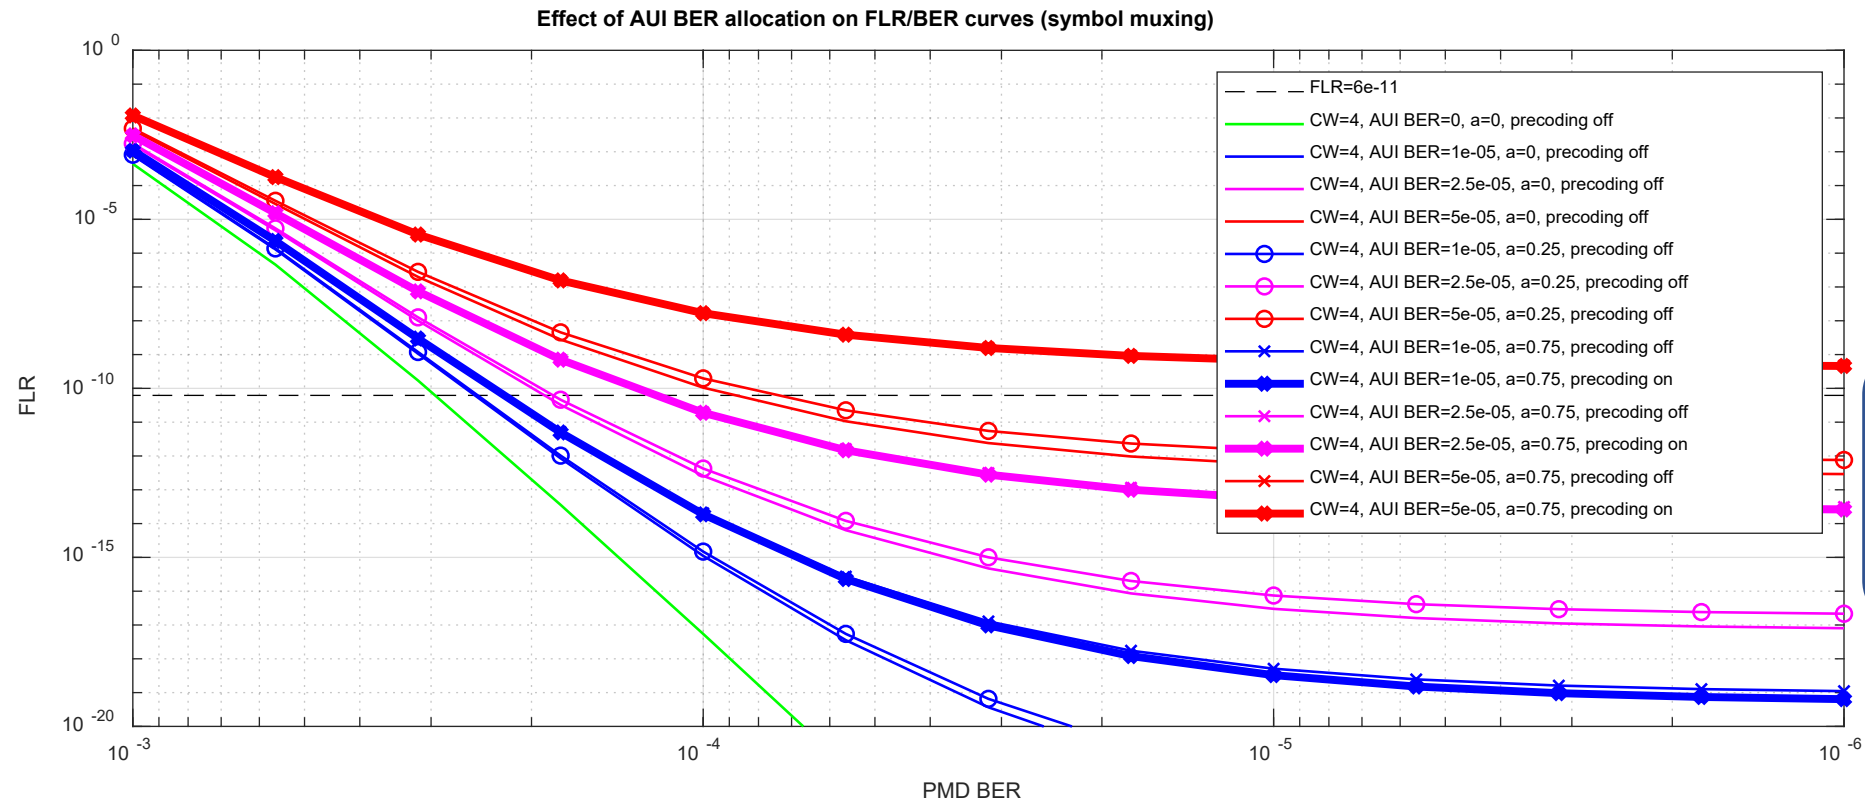

“FLR floor” still observed with AUI BER > 5e-5, and with 2.5e-5 and a=0.75

Effect of precoding with 2-CW interleaving

With severe error correlation ($a=0.75$), precoding (thick line plots) somewhat reduces the FLR floor

Effect of precoding with 4-CW interleaving

Precoding (thick line plots) has negligible effect.

Summary

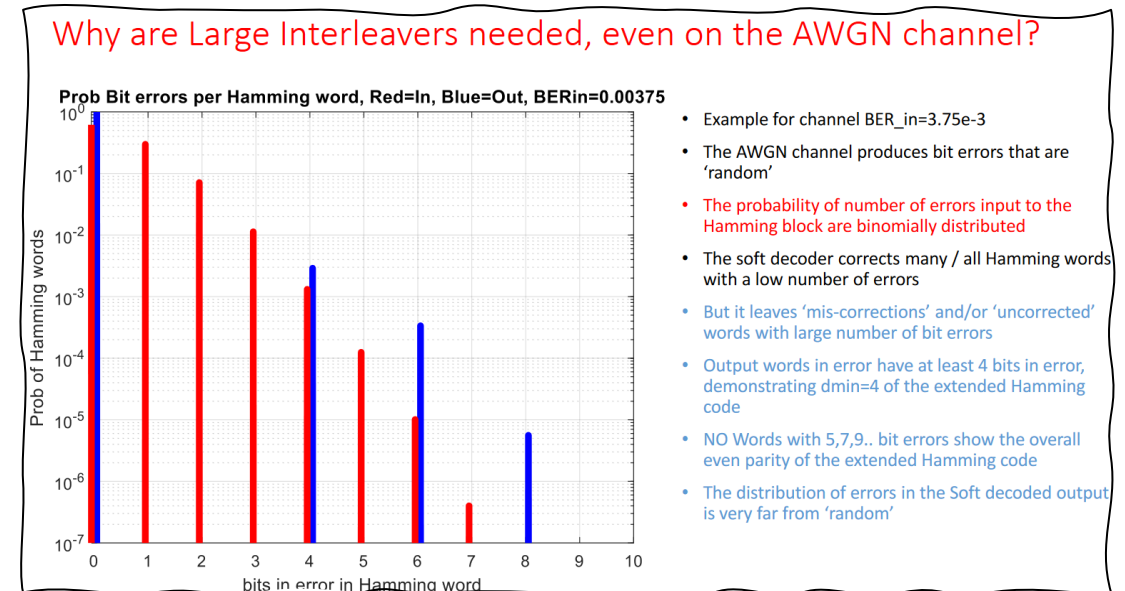

- 2-way RS-FEC interleaving is very sensitive to correlated errors in the AUI
 - $a=0.75$ on the AUIs flattens the FLR curve even with BER $1e-5$
 - Performance with AUI BER of $1e-5$ is similar to $2.5e-5$ with 4-way interleaving
 - → **Additional PMA codeword interleaving for 200G/400G is recommended**
- With 4-way interleaving, precoding has little effect and is not required
- AUI BER allocation can have a large impact on PMD BER:
 - $1e-5$ per AUI (or $2e-5$ per PHY) even with $a=0.75$ enables meeting the $6.2e-11$ FLR target with **PMD BER of $\sim 2.2e-4$ (almost no reduction) and does not create an FLR floor**
 - $2.5e-5$ per AUI (or $5e-5$ per PHY) with $a=0.75$ enables meeting the $6.2e-11$ FLR target but with **a reduction of the PMD BER by a factor of 2.5**
 - That is, from $3e-4$ to $1.2e-4$ (after inner FEC decoding)
 - This case as an FLR floor at $\sim 1e-14$, which may be unacceptable
 - BER above $5e-5$ per PHY **creates a high FLR floor, making low FLR unachievable**
 - If AUIs have these BER levels, they can be used within a xGMII Extender

What is the BER of the optical link?

Error characteristics of Inner FEC code

- $D_{min}=4$
- Hard decoder can always correct a block with a single-bit error (one “bad sample”)
- Blocks with 2 “bit errors” can be changed to either of two neighbors (either 0 or 4 output bit errors)
- Soft decoder can correct more errors on average, but occasionally create more errors
 - Blocks with 8 bit errors occur with non negligible probability
- If the convolutional interleaver is not used, this can cause up to 6 symbol errors in one codeword (2-CW case)
- The effect of these multi-error events without interleaving is planned to be explored in a future analysis.
