Where Information Flows.™

Link Aggregation Configuration

By Paul A. Bottorff

For April 1998 IEEE Meeting

A Few Consequences Of Compatibility

- A link supporting Link Aggregation must be able to operate like a normal link if not entering a Link Group.
- Any PDUs generated by Aggregation Control must be absorbed and disregarded by Non-Aggregating links.
- MAC Clients may attach to either a “physical” interface or a “logical” interface.

Bay Networks

Where Information Flows™

Active Non-Aggregated Link

- Before binding to a MUX Aggregation Control may bind to a MAC Client
- The MAC Client uses the “physical” address
- Aggregation Control may intercept control frames

Bay Networks

Where Information Flows™

Active Aggregated Link

- Aggregation Control bound to a MUX
- MAC Client using the “logical” or MUX address
- Aggregation Control may intercept control frames

Bay Networks

Where Information Flows™

Can 2 Clients Bind To 1 Link?

- Both “Physical” and “Logical” addresses
- Multicast frames must be duplicated?
- Only one promiscuous receiver
- “Logical” and “Physical” interfaces different

Bay Networks

Where Information Flows™

Single Client

ACTIVE, NOT AGGREGATING

State Change

ACTIVE, AGGREGATING

- Example where aggregating state change requires coupling a MUX
- Probably need a transition through NOT ACTIVE state

Bay Networks

Where Information Flows™

Single Address Case

ACTIVE, NOT AGGREGATING

State Change

ACTIVE, AGGREGATING

- If this is the first link entering an aggregation, then it's MUX will define the group
- In this case a “physical” address is re-used for the “logical” address

Bay Networks

Where Information Flows™

Single Client Model

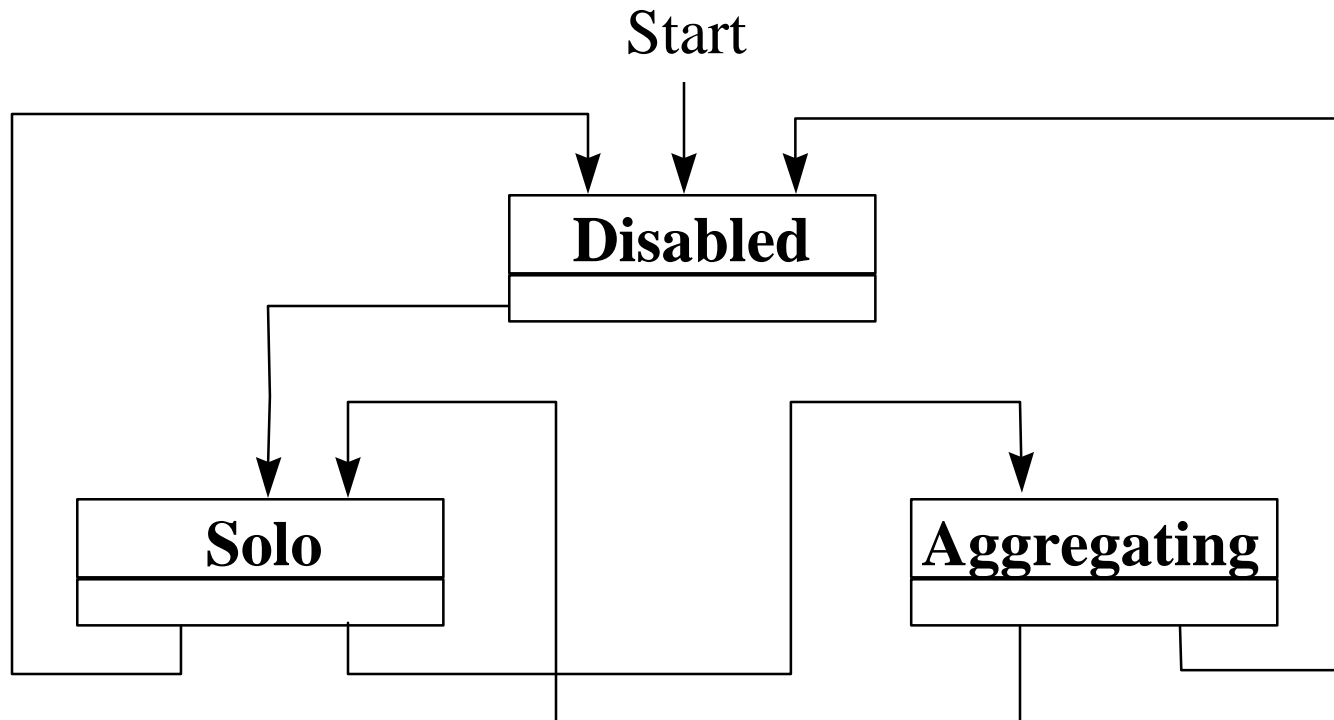

- **Switches modes between Non-Aggregating and Aggregating state**
- **May have a single MAC address for “logical” and “physical”**
- **When using separate “physical” and “logical” MAC addresses and when a client is attached to the “logical” address the “physical” address is only used by the MAC Aggregation Control Layer**

Bay Networks

Where Information Flows™

Single Client Control States

- **Disabled = MAC Inoperative**
- **Solo = MAC Operative & Not Associated With MUX**
- **Aggregating = MAC Operative & Associated With MUX**

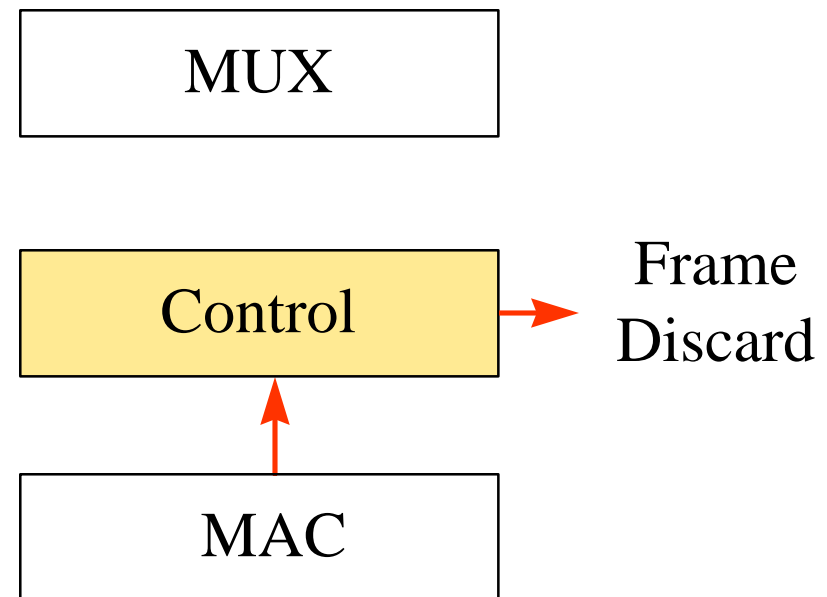

Bay Networks

Where Information Flows.™

Disabled State

- When the control state is Disabled all frames received are discarded

Bay Networks

Where Information Flows™

Solo State

- When the control state is Solo Control Frames are intercepted
- All other frames may forward to the MAC Client
-

Bay Networks

Where Information Flows™

Aggregating State

- When the control state is Aggregating Control Frames are intercepted
- All other frames are forwarded to the MUX
-

Bay Networks

Where Information Flows™

Recommendation

- **Adopt a Single Client model**
