

Packet Bursting

**Mart Molle, Jayant Kadambi, Mohan Kalkunte, and
Howard Frazier**

-
- **The following people have indicated support for this proposal**
 - **Moti Weizman**
 - **Dave Fifield**
 - **Steve Haddock**

Overview

- **Carrier Extension & Packet Packing**
- **Packet Bursting Overview**
- **Simulation Results**
- **Summary and Observations**

Objective

- **Improve shared 1000 Mbps performance to make it an attractive option to enable inexpensive gigabit networks**
- **Minimize transmitter and receiver complexity to enable this**
- **Requires only a minimal change to original Carrier Extension proposal**

Current Situation

- **Carrier Extension “wastes” up to 448 bytes for small packets resulting in low throughput performance**
 - Only marginally better than shared 100Mbps for small packet sizes
- **Packet Packing improves performance significantly for 64 byte packets at all offered loads and at high offered loads for the workgroup distribution**
 - Requires receiver to discard multiple packets after a collision
 - Increases complexity of statistics collection since both transmitter and receiver must delay updates until end of slot time

Solution: Packet Bursting

- Packet Bursting is carrier extension plus a burst of packets
- Station transmissions are padded to slot time if necessary using carrier extension
- Subsequent to slot time, stations transmit packets with minimum IPG spacing until burst timer (1500 bytes) expires
 - Collision window has passed, so stations are guaranteed there are no collisions

Packet Burst Timing

Packet Bursting

- **As with baseline carrier extension, receiver is guaranteed to see only one packet during collision window.**
- **Subsequently, RXDV will delimit further packets**
 - **All these packets are guaranteed not to collide**
- **The de-assertion of CRS ends reception**
- **Maximum duration of carrier event is two 1500 byte packets**

Simulation Environment

-
- 1000 Mbps network
 - 15 stations
 - 512 byte slot times
 - 200 m network diameter
 - Packet size distributions
 - All 64 bytes
 - All 1500 bytes
 - Workgroup Average

Performance Measures

- **Performance characterized in terms of**
 - **Network Throughput**
 - » Amount of traffic the network can carry under the given offered load
 - **Collision Likelihood**
 - » Probability that a packet experiences one or more collisions
 - **Deference Likelihood**
 - » Probability that a packet waits upon arrival at the MAC
 - **Number of consecutive packets**
 - » The number of consecutive packets a station transmits on the network until there is a receive on the wire
 - **Access Latency**
 - » Waiting time of a frame when it is the head of the MAC queue until successful transmission or discard

Simulation Results

15 Stations, 100% offered load, Total Network Throughput (Data Utilization)

<i>Packet Size</i>	<i>Reference</i>	<i>Packet Packing</i>	<i>Packet Bursting</i>
<i>64 bytes</i>	<i>90.68 Mbps</i>	<i>339.84 Mbps</i>	<i>286.75 Mbps</i>
<i>1500 bytes</i>	<i>853.20 Mbps</i>	<i>853.20 Mbps</i>	<i>853.20 Mbps</i>
<i>Workgroup Distribution¹</i>	<i>562.19 Mbps</i>	<i>740.80 Mbps</i>	<i>700.32 Mbps</i>

1. Distribution data collected by Howard Frazier that averaged workgroup traffic across 10Mbps and 100Mbps networks

Simulation Results

Network Throughput Vs. Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Note: The network throughput indicated here is data throughput

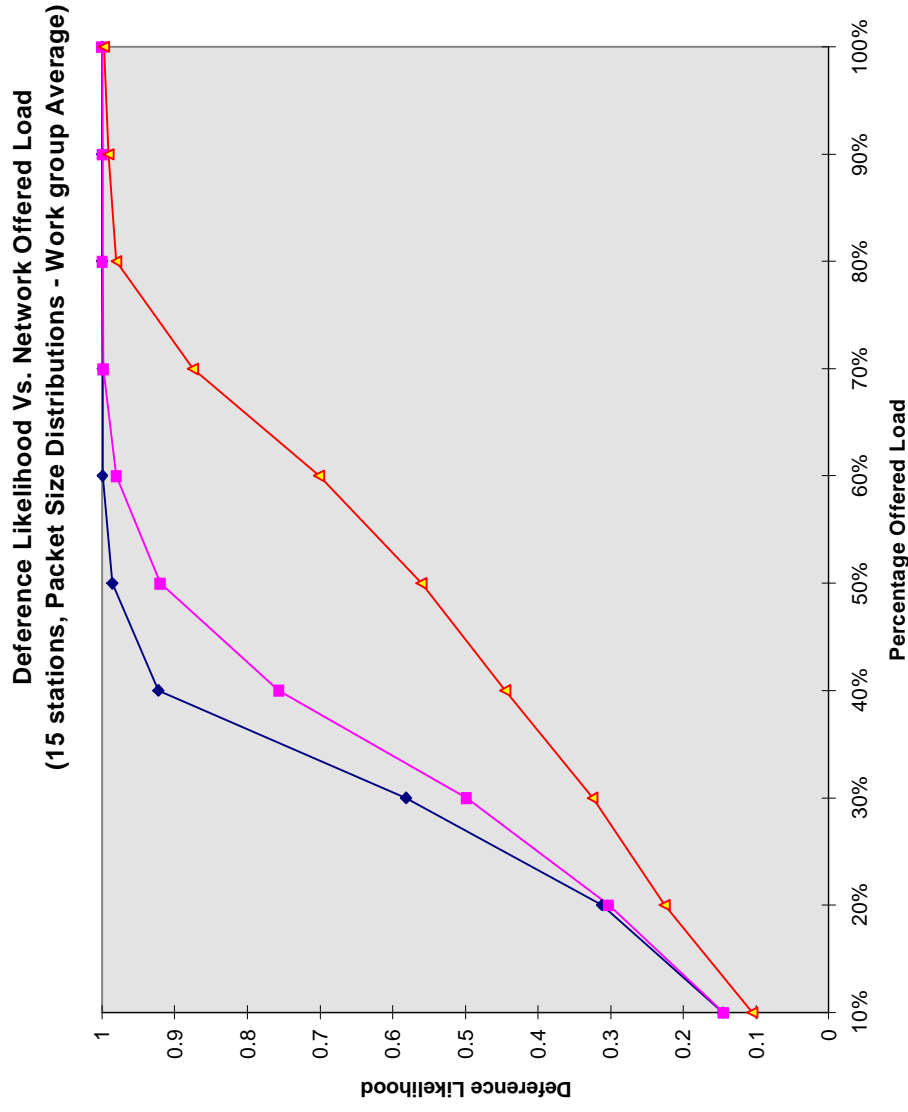

Simulation Results

Collision Likelihood Vs. Network Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

Simulation Results

Average End-End Packet Delay Vs. Network Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

Percentage of Packets > AttemptLimit Vs. Network Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

Mean Access Latency at 30% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

Mean Access Latency at 40% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

Mean Access Latency at 50% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Access Latency Comparison at 30% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Access Latency Comparison at 40% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Access Latency Comparison at 50% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Station Consecutive Transmits at 30% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Station Consecutive Transmits at 40% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Simulation Results

95th Percentile Station Consecutive Transmits at 50% Offered Load
(15 stations, Packet Size Distributions - Work group Average)

Results Summary

-
- **PB provides three times more throughput for small packets than baseline**
 - **PB improves throughput by 25% for workgroup packet size distribution**
 - **PB delays the capture effect to happen at higher offered loads than baseline**
 - **PB improves all measures of performance for workgroup**

Summary & Observations

- **Packet Bursting provides a performance improvement similar to that of packet packing**
 - **makes shared gigabit Ethernet an attractive option**
- **Packet Bursting does not require receivers and transmitters to hold multiple packets or statistics till end of collision window**
- **Packet Bursting requires minimal changes in MAC Pascal with Carrier Extension**
 - **addition of burst length timer, a receiver flag and a transmit state variable**

Summary & Observations

-
- **No change to repeaters**
 - **Repeats everything after CRS assertion until CRS de-assertion**
 - **Oblivious to packet bursting**
